## nag\_fft\_multid\_single (c06pfc)

### 1 Purpose

nag\_fft\_multid\_single (c06pfc) computes the discrete Fourier transform of one variable in a multivariate sequence of complex data values.

### 2 Specification

```
#include <nag.h>
#include <nagc06.h>

void nag_fft_multid_single (Nag_TransformDirection direct, Integer ndim,
    Integer l, const Integer nd[], Integer n, Complex x[], NagError *fail)
```

### 3 Description

nag\_fft\_multid\_single (c06pfc) computes the discrete Fourier transform of one variable (the  $l$ th say) in a multivariate sequence of complex data values  $z_{j_1 j_2 \dots j_m}$ , where  $j_1 = 0, 1, \dots, n_1 - 1$ ,  $j_2 = 0, 1, \dots, n_2 - 1$ , and so on. Thus the individual dimensions are  $n_1, n_2, \dots, n_m$ , and the total number of data values is  $n = n_1 \times n_2 \times \dots \times n_m$ .

The function computes  $n/n_l$  one-dimensional transforms defined by

$$\hat{z}_{j_1 \dots k_l \dots j_m} = \frac{1}{\sqrt{n_l}} \sum_{j_l=0}^{n_l-1} z_{j_1 \dots j_l \dots j_m} \times \exp\left(\pm \frac{2\pi i j_l k_l}{n_l}\right),$$

where  $k_l = 0, 1, \dots, n_l - 1$ . The plus or minus sign in the argument of the exponential terms in the above definition determine the direction of the transform: a minus sign defines the **forward** direction and a plus sign defines the **backward** direction.

(Note the scale factor of  $\frac{1}{\sqrt{n_l}}$  in this definition.)

A call of nag\_fft\_multid\_single (c06pfc) with **direct** = Nag\_ForwardTransform followed by a call with **direct** = Nag\_BackwardTransform will restore the original data.

The data values must be supplied in a one-dimensional complex array using column-major storage ordering of multidimensional data (i.e., with the first subscript  $j_1$  varying most rapidly).

This function uses a variant of the fast Fourier transform (FFT) algorithm (see Brigham (1974)) known as the Stockham self-sorting algorithm, which is described in Temperton (1983).

### 5 Arguments

- 1: **direct** – Nag\_TransformDirection *Input*  
*On entry:* if the forward transform as defined in Section 3 is to be computed, then **direct** must be set equal to Nag\_ForwardTransform.

If the backward transform is to be computed then **direct** must be set equal to Nag\_BackwardTransform.

*Constraint:* **direct** = Nag\_ForwardTransform or Nag\_BackwardTransform.

- 2: **ndim** – Integer *Input*  
*On entry:*  $m$ , the number of dimensions (or variables) in the multivariate data.  
*Constraint:* **ndim**  $\geq 1$ .
- 3: **l** – Integer *Input*  
*On entry:*  $l$ , the index of the variable (or dimension) on which the discrete Fourier transform is to be performed.  
*Constraint:*  $1 \leq l \leq \mathbf{ndim}$ .
- 4: **nd[ndim]** – const Integer *Input*  
*On entry:* the elements of **nd** must contain the dimensions of the **ndim** variables; that is, **nd**[ $i - 1$ ] must contain the dimension of the  $i$ th variable.  
*Constraint:* **nd**[ $i - 1$ ]  $\geq 1$ , for  $i = 1, 2, \dots, \mathbf{ndim}$ .
- 5: **n** – Integer *Input*  
*On entry:*  $n$ , the total number of data values.  
*Constraint:* **n** must equal the product of the first **ndim** elements of the array **nd**.
- 6: **x[n]** – Complex *Input/Output*  
*On entry:* the complex data values. Data values are stored in **x** using column-major ordering for storing multidimensional arrays; that is,  $z_{j_1 j_2 \dots j_m}$  is stored in **x**[ $j_1 + n_1 j_2 + n_1 n_2 j_3 + \dots$ ].  
*On exit:* the corresponding elements of the computed transform.
- 7: **fail** – NagError \* *Input/Output*  
The NAG error argument (see Section 3.6 in the Essential Introduction).

## 6 Error Indicators and Warnings

### NE\_ALLOC\_FAIL

Dynamic memory allocation failed.

### NE\_BAD\_PARAM

On entry, argument  $\langle value \rangle$  had an illegal value.

### NE\_INT

On entry, **l** =  $\langle value \rangle$ .

*Constraint:* **l**  $\geq 1$  and **l**  $\leq \mathbf{ndim}$ .

On entry, **ndim** =  $\langle value \rangle$ .

*Constraint:* **ndim**  $\geq 1$ .

### NE\_INT\_2

**n** must equal the product of the dimensions held in array **nd**: **n** =  $\langle value \rangle$ , product of **nd** elements is  $\langle value \rangle$ .

On entry  $\mathbf{nd}[I - 1] = \langle \text{value} \rangle$  and  $I = \langle \text{value} \rangle$ .  
 Constraint:  $\mathbf{nd}[I - 1] \geq 1$ .

## NE\_INTERNAL\_ERROR

An internal error has occurred in this function. Check the function call and any array sizes. If the call is correct then please contact NAG for assistance.

## 7 Accuracy

Some indication of accuracy can be obtained by performing a subsequent inverse transform and comparing the results with the original sequence (in exact arithmetic they would be identical).

## 8 Parallelism and Performance

`nag_fft_multid_single` (c06pfc) is threaded by NAG for parallel execution in multithreaded implementations of the NAG Library.

`nag_fft_multid_single` (c06pfc) makes calls to BLAS and/or LAPACK routines, which may be threaded within the vendor library used by this implementation. Consult the documentation for the vendor library for further information.

Please consult the Users' Note for your implementation for any additional implementation-specific information.

## 9 Further Comments

The time taken is approximately proportional to  $n \times \log n_l$ , but also depends on the factorization of  $n_l$ . `nag_fft_multid_single` (c06pfc) is faster if the only prime factors of  $n_l$  are 2, 3 or 5; and fastest of all if  $n_l$  is a power of 2.

## 10 Example

This example reads in a bivariate sequence of complex data values and prints the discrete Fourier transform of the second variable. It then performs an inverse transform and prints the sequence so obtained, which may be compared with the original data values.
