

NAG Library Function Document

nag_1d_quad_wt_alglog_1 (d01spc)

1 Purpose

nag_1d_quad_wt_alglog_1 (d01spc) is an adaptive integrator which calculates an approximation to the integral of a function $g(x)w(x)$ over a finite interval $[a, b]$:

$$I = \int_a^b g(x)w(x)dx$$

where the weight function w has end-point singularities of algebraico-logarithmic type.

2 Specification

```
#include <nag.h>
#include <nagd01.h>
void nag_1d_quad_wt_alglog_1 (
    double (*g)(double x, Nag_User *comm),
    double a, double b, double alfa, double beta, Nag_QuadWeight wt_func,
    double epsabs, double epsrel, Integer max_num_subint, double *result,
    double *abserr, Nag_QuadProgress *qp, Nag_User *comm, NagError *fail)
```

3 Description

nag_1d_quad_wt_alglog_1 (d01spc) is based upon the QUADPACK routine QAWSE (Piessens *et al.* (1983)) and integrates a function of the form $g(x)w(x)$, where the weight function $w(x)$ may have algebraico-logarithmic singularities at the end-points a and/or b . The strategy is a modification of that in nag_1d_quad_osc_1 (d01skc). We start by bisecting the original interval and applying modified Clenshaw–Curtis integration of orders 12 and 24 to both halves. Clenshaw–Curtis integration is then used on all sub-intervals which have a or b as one of their end-points (Piessens *et al.* (1974)). On the other sub-intervals Gauss–Kronrod (7–15 point) integration is carried out.

A ‘global’ acceptance criterion (as defined by Malcolm and Simpson (1976)) is used. The local error estimation control is described by Piessens *et al.* (1983).

5 Arguments

- 1: **g** – function, supplied by the user *External Function*
g must return the value of the function g at a given point.
- The specification of **g** is:

```
double g (double x, Nag_User *comm)
```

1: **x** – double *Input*
On entry: the point at which the function g must be evaluated.

2: **comm** – Nag_User *
 Pointer to a structure of type Nag_User with the following member:
p – Pointer
On entry/exit: the pointer **comm**–**p** should be cast to the required type, e.g.,
`struct user *s = (struct user *)comm → p;`, to obtain the original
 object's address with appropriate type. (See the argument **comm** below.)
- 2: **a** – double *Input*
On entry: the lower limit of integration, a .
- 3: **b** – double *Input*
On entry: the upper limit of integration, b .
Constraint: **b** > **a**.
- 4: **alfa** – double *Input*
On entry: the argument α in the weight function.
Constraint: **alfa** > -1.0 .
- 5: **beta** – double *Input*
On entry: the argument β in the weight function.
Constraint: **beta** > -1.0 .
- 6: **wt_func** – Nag_QuadWeight *Input*
On entry: indicates which weight function is to be used:
 if **wt_func** = Nag_Alg, $w(x) = (x - a)^\alpha(b - x)^\beta$;
 if **wt_func** = Nag_Alg_loga, $w(x) = (x - a)^\alpha(b - x)^\beta \ln(x - a)$;
 if **wt_func** = Nag_Alg_logb, $w(x) = (x - a)^\alpha(b - x)^\beta \ln(b - x)$;
 if **wt_func** = Nag_Alg_loga_logb, $w(x) = (x - a)^\alpha(b - x)^\beta \ln(x - a) \ln(b - x)$.
Constraint: **wt_func** = Nag_Alg, Nag_Alg_loga, Nag_Alg_logb or Nag_Alg_loga_logb.
- 7: **epsabs** – double *Input*
On entry: the absolute accuracy required. If **epsabs** is negative, the absolute value is used. See Section 7.

| | | |
|--|---------------------------------|---------------------|
| 8: | epsrel – double | <i>Input</i> |
| <i>On entry:</i> the relative accuracy required. If epsrel is negative, the absolute value is used. See Section 7. | | |
| 9: | max_num_subint – Integer | <i>Input</i> |
| <i>On entry:</i> the upper bound on the number of sub-intervals into which the interval of integration may be divided by the function. The more difficult the integrand, the larger max_num_subint should be. | | |
| <i>Constraint:</i> max_num_subint ≥ 2 . | | |
| 10: | result – double * | <i>Output</i> |
| <i>On exit:</i> the approximation to the integral I . | | |
| 11: | abserr – double * | <i>Output</i> |
| <i>On exit:</i> an estimate of the modulus of the absolute error, which should be an upper bound for $ I - \text{result} $. | | |
| 12: | qp – Nag_QuadProgress * | |
| Pointer to structure of type Nag_QuadProgress with the following members: | | |
| num_subint – Integer | | <i>Output</i> |
| <i>On exit:</i> the actual number of sub-intervals used. | | |
| fun_count – Integer | | <i>Output</i> |
| <i>On exit:</i> the number of function evaluations performed by nag_1d_quad_wt_alglog_1 (d01spc). | | |
| sub_int_beg_pts – double * | | <i>Output</i> |
| sub_int_end_pts – double * | | <i>Output</i> |
| sub_int_result – double * | | <i>Output</i> |
| sub_int_error – double * | | <i>Output</i> |
| <i>On exit:</i> these pointers are allocated memory internally with max_num_subint elements. If an error exit other than NE_INT_ARG_LT, NE_BAD_PARAM, NE_REAL_ARG_LE, NE_2_REAL_ARG_LE or NE_ALLOC_FAIL occurs, these arrays will contain information which may be useful. For details, see Section 9. | | |
| Before a subsequent call to nag_1d_quad_wt_alglog_1 (d01spc) is made, or when the information contained in these arrays is no longer useful, you should free the storage allocated by these pointers using the NAG macro NAG_FREE. | | |
| 13: | comm – Nag_User * | |
| Pointer to a structure of type Nag_User with the following member: | | |
| p – Pointer | | |
| <i>On entry/exit:</i> the pointer comm – p , of type Pointer, allows you to communicate information to and from g(). An object of the required type should be declared, e.g., a structure, and its address assigned to the pointer comm – p by means of a cast to Pointer in the calling program, e.g., comm.p = (Pointer)&s. The type Pointer is void *. | | |
| 14: | fail – NagError * | <i>Input/Output</i> |
| The NAG error argument (see Section 3.6 in the Essential Introduction). | | |

6 Error Indicators and Warnings

NE_2_REAL_ARG_LE

On entry, **b** = $\langle value \rangle$ while **a** = $\langle value \rangle$. These arguments must satisfy **b** > **a**.

NE_ALLOC_FAIL

Dynamic memory allocation failed.

NE_BAD_PARAM

On entry, argument **wt_func** had an illegal value.

NE_INT_ARG_LT

On entry, **max_num_subint** must not be less than 2: **max_num_subint** = $\langle value \rangle$.

NE_QUAD_BAD_SUBDIV

Extremely bad integrand behaviour occurs around the sub-interval $(\langle value \rangle, \langle value \rangle)$.

The same advice applies as in the case of NE_QUAD_MAX_SUBDIV.

NE_QUAD_MAX_SUBDIV

The maximum number of subdivisions has been reached: **max_num_subint** = $\langle value \rangle$.

The maximum number of subdivisions has been reached without the accuracy requirements being achieved. Look at the integrand in order to determine the integration difficulties. If the position of a discontinuity or a singularity of algebraico-logarithmic type within the interval can be determined, the interval must be split up at this point and the integrator called on the sub-intervals. If necessary, another integrator, which is designed for handling the type of difficulty involved, must be used. Alternatively, consider relaxing the accuracy requirements specified by **epsabs** and **epsrel**, or increasing the value of **max_num_subint**.

NE_QUAD_ROUNDOFF_TOL

Round-off error prevents the requested tolerance from being achieved: **epsabs** = $\langle value \rangle$, **epsrel** = $\langle value \rangle$.

The error may be underestimated. Consider relaxing the accuracy requirements specified by **epsabs** and **epsrel**.

NE_REAL_ARG_LE

On entry, **alfa** = $\langle value \rangle$.

Constraint: **alfa** ≤ -1.0 .

On entry, **beta** = $\langle value \rangle$.

Constraint: **beta** ≤ -1.0 .

7 Accuracy

`nag_1d_quad_wt_alglog_1` (d01spc) cannot guarantee, but in practice usually achieves, the following accuracy:

$$|I - \mathbf{result}| \leq tol$$

where $tol = \max\{|\mathbf{epsabs}|, |\mathbf{epsrel}| \times |I|\}$ and **epsabs** and **epsrel** are user-specified absolute and relative error tolerances. Moreover it returns the quantity **abserr** which, in normal circumstances, satisfies

$$|I - \mathbf{result}| \leq \mathbf{abserr} \leq tol.$$

8 Parallelism and Performance

Not applicable.

9 Further Comments

The time taken by nag_1d_quad_wt_alglog_1 (d01spc) depends on the integrand and the accuracy required.

If the function fails with an error exit other than NE_INT_ARG_LT, NE_BAD_PARAM, NE_REAL_ARG_LE, NE_2_REAL_ARG_LE or NE_ALLOC_FAIL then you may wish to examine the contents of the structure **qp**. These contain the end-points of the sub-intervals used by nag_1d_quad_wt_alglog_1 (d01spc) along with the integral contributions and error estimates over these sub-intervals.

Specifically, $i = 1, 2, \dots, n$, let r_i denote the approximation to the value of the integral over the sub-interval $[a_i, b_i]$ in the partition of $[a, b]$ and e_i be the corresponding absolute error estimate.

Then, $\int_{a_i}^{b_i} g(x)w(x)dx \simeq r_i$ and **result** = $\sum_{i=1}^n r_i$.

The value of n is returned in **qp**→**num_subint**, and the values a_i , b_i , r_i and e_i are stored in the structure **qp** as

$$\begin{aligned} a_i &= \mathbf{qp} \rightarrow \mathbf{sub_int_beg_pts}[i - 1], \\ b_i &= \mathbf{qp} \rightarrow \mathbf{sub_int_end_pts}[i - 1], \\ r_i &= \mathbf{qp} \rightarrow \mathbf{sub_int_result}[i - 1] \text{ and} \\ e_i &= \mathbf{qp} \rightarrow \mathbf{sub_int_error}[i - 1]. \end{aligned}$$

10 Example

This example computes

$$\int_0^1 \ln x \cos(10\pi x) dx$$

and

$$\int_0^1 \frac{\sin(10x)}{\sqrt{x(1-x)}} dx.$$
