NAG Library Function Document nag_robust_m_regsn_wts (g02hbc)

1 Purpose

nag_robust_m_regsn_wts (g02hbc) finds, for a real matrix X of full column rank, a lower triangular matrix A such that $(A^TA)^{-1}$ is proportional to a robust estimate of the covariance of the variables. nag_robust_m_regsn_wts (g02hbc) is intended for the calculation of weights of bounded influence regression using nag robust m regsn user fn (g02hdc).

2 Specification

3 Description

In fitting the linear regression model

$$y = X\theta + \epsilon$$
,

where y is a vector of length n of the dependent variable,

X is an n by m matrix of independent variables,

 θ is a vector of length m of unknown arguments,

and ϵ is a vector of length n of unknown errors,

it may be desirable to bound the influence of rows of the X matrix. This can be achieved by calculating a weight for each observation. Several schemes for calculating weights have been proposed (see Hampel et al. (1986) and Marazzi (1987)). As the different independent variables may be measured on different scales one group of proposed weights aims to bound a standardized measure of influence. To obtain such weights the matrix A has to be found such that

$$\frac{1}{n} \sum_{i=1}^{n} u(\|z_i\|_2) z_i z_i^{\mathsf{T}} = I \quad (I \text{ is the identity matrix})$$

and

$$z_i = Ax_i$$

where x_i is a vector of length m containing the elements of the ith row of X,

A is an m by m lower triangular matrix,

 z_i is a vector of length m,

and u is a suitable function.

The weights for use with nag robust m regsn user fn (g02hdc) may then be computed using

$$w_i = f(\|z_i\|_2)$$

for a suitable user-supplied function f.

nag robust m regsn wts (g02hbc) finds A using the iterative procedure

$$A_k = (S_k + I)A_{k-1},$$

where $S_k = (s_{il})$, for i = 1, 2, ..., m and l = 1, 2, ..., m, is a lower triangular matrix such that

$$s_{jl} = \begin{cases} -\min[\max(h_{jl}/n, -BL), BL], & j > l \\ -\min[\max(\frac{1}{2}(h_{jj}/n - 1), -BD), BD], & j = l \end{cases}$$

$$h_{jl} = \sum_{i=1}^{n} u(\|z_i\|_2) z_{ij} z_{il}$$

and BD and BL are suitable bounds.

In addition the values of $||z_i||_2$, for i = 1, 2, ..., n, are calculated.

nag robust m_regsn_wts (g02hbc) is based on routines in ROBETH; see Marazzi (1987).

5 Arguments

1: **order** – Nag OrderType

Input

On entry: the **order** argument specifies the two-dimensional storage scheme being used, i.e., row-major ordering or column-major ordering. C language defined storage is specified by **order** = Nag_RowMajor. See Section 3.2.1.3 in the Essential Introduction for a more detailed explanation of the use of this argument.

Constraint: order = Nag_RowMajor or Nag_ColMajor.

2: **ucv** – function, supplied by the user

External Function

Input

ucv must return the value of the function u for a given value of its argument. The value of u must be non-negative.

The specification of ucv is:

double ucv (double t, Nag_Comm *comm)

1: \mathbf{t} - double

On entry: the argument for which ucv must be evaluated.

2: **comm** – Nag_Comm * Communication Structure

Pointer to structure of type Nag_Comm; the following members are relevant to ucv.

g02hbc.2 Mark 24

```
user - double *
iuser - Integer *
p - Pointer
```

The type Pointer will be <code>void *</code>. Before calling nag_robust_m_regsn_wts (g02hbc) you may allocate memory and initialize these pointers with various quantities for use by **ucv** when called from nag_robust_m_regsn_wts (g02hbc) (see Section 3.2.1.1 in the Essential Introduction).

3: **n** – Integer

On entry: n, the number of observations.

Constraint: $\mathbf{n} > 1$.

4: \mathbf{m} – Integer Input

On entry: m, the number of independent variables.

Constraint: $1 \leq \mathbf{m} \leq \mathbf{n}$.

5: $\mathbf{x}[dim]$ – const double Input

Note: the dimension, dim, of the array x must be at least

```
\max(1, \mathbf{pdx} \times \mathbf{m}) when \mathbf{order} = \text{Nag\_ColMajor}; \max(1, \mathbf{n} \times \mathbf{pdx}) when \mathbf{order} = \text{Nag\_RowMajor}.
```

Where $\mathbf{X}(i,j)$ appears in this document, it refers to the array element

```
\mathbf{x}[(j-1) \times \mathbf{pdx} + i - 1] when \mathbf{order} = \text{Nag\_ColMajor};
\mathbf{x}[(i-1) \times \mathbf{pdx} + j - 1] when \mathbf{order} = \text{Nag\_RowMajor}.
```

On entry: the real matrix X, i.e., the independent variables. $\mathbf{X}(i,j)$ must contain the ijth element of \mathbf{x} , for $i=1,2,\ldots,n$ and $j=1,2,\ldots,m$.

6: **pdx** – Integer Input

On entry: the stride separating row or column elements (depending on the value of **order**) in the array \mathbf{x} .

Constraints:

```
if order = Nag_ColMajor, pdx \ge n; if order = Nag_RowMajor, pdx \ge m.
```

7:
$$\mathbf{a}[\mathbf{m} \times (\mathbf{m} + \mathbf{1})/2] - \text{double}$$

Input/Output

On entry: an initial estimate of the lower triangular real matrix A. Only the lower triangular elements must be given and these should be stored row-wise in the array.

The diagonal elements must be $\neq 0$, although in practice will usually be > 0. If the magnitudes of the columns of X are of the same order the identity matrix will often provide a suitable initial value for A. If the columns of X are of different magnitudes, the diagonal elements of the initial value of A should be approximately inversely proportional to the magnitude of the columns of X.

On exit: the lower triangular elements of the matrix A, stored row-wise.

8: $\mathbf{z}[\mathbf{n}]$ – double

On exit: the value $||z_i||_2$, for i = 1, 2, ..., n.

9: **bl** – double *Input*

On entry: the magnitude of the bound for the off-diagonal elements of S_k .

Suggested value: $\mathbf{bl} = 0.9$.

Constraint: bl > 0.0.

10: **bd** – double Input

On entry: the magnitude of the bound for the diagonal elements of S_k .

Suggested value: $\mathbf{bd} = 0.9$.

Constraint: bd > 0.0.

11: **tol** – double *Input*

On entry: the relative precision for the final value of A. Iteration will stop when the maximum value of $|s_{il}|$ is less than **tol**.

Constraint: tol > 0.0.

12: maxit – Integer Input

On entry: the maximum number of iterations that will be used during the calculation of A.

A value of $\mathbf{maxit} = 50$ will often be adequate.

Constraint: maxit > 0.

13: **nitmon** – Integer Input

On entry: determines the amount of information that is printed on each iteration.

nitmon > 0

The value of A and the maximum value of $|s_{jl}|$ will be printed at the first and every **nitmon** iterations.

 $nitmon \leq 0$

No iteration monitoring is printed.

14: **outfile** – const char * Input

On entry: a null terminated character string giving the name of the file to which results should be printed. If **outfile = NULL** or an empty string then the stdout stream is used. Note that the file will be opened in the append mode.

15: **nit** – Integer * Output

On exit: the number of iterations performed.

16: **comm** – Nag_Comm * Communication Structure

The NAG communication argument (see Section 3.2.1.1 in the Essential Introduction).

17: fail – NagError * Input/Output

The NAG error argument (see Section 3.6 in the Essential Introduction).

6 Error Indicators and Warnings

NE_ALLOC_FAIL

Dynamic memory allocation failed.

NE BAD PARAM

On entry, argument $\langle value \rangle$ had an illegal value.

g02hbc.4 Mark 24

NE CONVERGENCE

Iterations to calculate weights failed to converge in **maxit** iterations: $maxit = \langle value \rangle$.

NE FUN RET VAL

Value returned by **ucv** function $\langle 0: u(\langle value \rangle) = \langle value \rangle$.

NE INT

```
On entry, \mathbf{maxit} = \langle value \rangle.
Constraint: \mathbf{maxit} > 0.
On entry, \mathbf{n} = \langle value \rangle.
Constraint: \mathbf{n} > 1.
On entry, \mathbf{pdx} = \langle value \rangle.
Constraint: \mathbf{pdx} > 0.
```

NE_INT_2

```
On entry, \mathbf{m} = \langle value \rangle and \mathbf{n} = \langle value \rangle.
Constraint: 1 \leq \mathbf{m} \leq \mathbf{n}.
On entry, \mathbf{pdx} = \langle value \rangle and \mathbf{m} = \langle value \rangle.
Constraint: \mathbf{pdx} \geq \mathbf{m}.
```

NE INTERNAL ERROR

An internal error has occurred in this function. Check the function call and any array sizes. If the call is correct then please contact NAG for assistance.

NE_NOT_CLOSE_FILE

Cannot close file \(\text{value} \).

NE_NOT_WRITE_FILE

Cannot open file $\langle value \rangle$ for writing.

NE REAL

```
On entry, \mathbf{bd} = \langle value \rangle.
Constraint: \mathbf{bd} > 0.0.
On entry, \mathbf{bl} = \langle value \rangle.
Constraint: \mathbf{bl} > 0.0.
On entry, \mathbf{tol} = \langle value \rangle.
Constraint: \mathbf{tol} > 0.0.
```

NE ZERO DIAGONAL

On entry, diagonal element $\langle value \rangle$ of **a** is 0.

7 Accuracy

On successful exit the accuracy of the results is related to the value of tol; see Section 5.

8 Parallelism and Performance

nag_robust_m_regsn_wts (g02hbc) is not threaded by NAG in any implementation.

nag_robust_m_regsn_wts (g02hbc) makes calls to BLAS and/or LAPACK routines, which may be threaded within the vendor library used by this implementation. Consult the documentation for the vendor library for further information.

Please consult the Users' Note for your implementation for any additional implementation-specific information

9 Further Comments

The existence of A will depend upon the function u; (see Hampel *et al.* (1986) and Marazzi (1987)), also if X is not of full rank a value of A will not be found. If the columns of X are almost linearly related then convergence will be slow.

10 Example

This example reads in a matrix of real numbers and computes the Krasker-Welsch weights (see Marazzi (1987)). The matrix A and the weights are then printed.
