

NAG Library Function Document

nag_tsa_spectrum_univar (g13cbc)

1 Purpose

nag_tsa_spectrum_univar (g13cbc) calculates the smoothed sample spectrum of a univariate time series using spectral smoothing by the trapezium frequency (Daniell) window.

2 Specification

```
#include <nag.h>
#include <nagg13.h>
void nag_tsa_spectrum_univar (Integer nx, NagMeanOrTrend mt_correction,
                               double px, Integer mw, double pw, Integer l, Integer kc,
                               Nag_LoggedSpectra lg_spect, const double x[], double **g, Integer *ng,
                               double stats[], NagError *fail)
```

3 Description

The supplied time series may be mean or trend corrected (by least squares), and tapered, the tapering factors being those of the split cosine bell:

$$\begin{aligned} \frac{1}{2} \left(1 - \cos \left(\frac{\pi(t-\frac{l}{2})}{T} \right) \right), & \quad 1 \leq t \leq T \\ \frac{1}{2} \left(1 - \cos \left(\frac{\pi(n-t+\frac{l}{2})}{T} \right) \right), & \quad n+1-T \leq t \leq n \\ 1, & \quad \text{otherwise} \end{aligned}$$

where $T = \lceil \frac{np}{2} \rceil$ and p is the tapering proportion.

The unsmoothed sample spectrum

$$f^*(\omega) = \frac{1}{2}\pi \left| \sum_{t=1}^n x_t \exp(i\omega t) \right|^2$$

is then calculated for frequency values

$$\omega_k = \frac{2\pi k}{K}, \quad k = 0, 1, \dots, [K/2]$$

where $[]$ denotes the integer part.

The smoothed spectrum is returned as a subset of these frequencies for which K is a multiple of a chosen value r , i.e.,

$$\omega_{rl} = \nu_l = \frac{2\pi l}{L}, \quad l = 0, 1, \dots, [L/2]$$

where $K = r \times L$. You will normally fix L first, then choose r so that K is sufficiently large to provide an adequate representation for the unsmoothed spectrum, i.e., $K \geq 2 \times n$. It is possible to take $L = K$, i.e., $r = 1$.

The smoothing is defined by a trapezium window whose shape is supplied by the function

$$\begin{aligned} W(\alpha) &= 1, & |\alpha| \leq p \\ W(\alpha) &= \frac{1-|\alpha|}{1-p}, & p < |\alpha| \leq 1 \end{aligned}$$

the proportion p being supplied by you.

The width of the window is fixed as $2\pi/M$ by supplying M . A set of averaging weights are constructed:

$$W_k = g \times W\left(\frac{\omega_k M}{\pi}\right), 0 \leq \omega_k \leq \frac{\pi}{M}$$

where g is a normalizing constant, and the smoothed spectrum obtained is

$$\hat{f}(\nu_l) = \sum_{|\omega_k| < \frac{\pi}{M}} W_k f^*(\nu_l + \omega_k).$$

If no smoothing is required M should be set to n , in which case the values returned are $\hat{f}(\nu_l) = f^*(\nu_l)$. Otherwise, in order that the smoothing approximates well to an integration, it is essential that $K \gg M$, and preferable, but not essential, that K be a multiple of M . A choice of $L > M$ would normally be required to supply an adequate description of the smoothed spectrum. Typical choices of $L \simeq n$ and $K \simeq 4n$ should be adequate for usual smoothing situations when $M < n/5$.

The sampling distribution of $\hat{f}(\omega)$ is approximately that of a scaled χ_d^2 variate, whose degrees of freedom d is provided by the function, together with multiplying limits mu , ml from which approximate 95% confidence intervals for the true spectrum $f(\omega)$ may be constructed as $[ml \times \hat{f}, (\omega), mu, \times, \hat{f}, (\omega)]$.

Alternatively, $\log \hat{f}(\omega)$ may be returned, with additive limits.

The bandwidth b of the corresponding smoothing window in the frequency domain is also provided. Spectrum estimates separated by (angular) frequencies much greater than b may be assumed to be independent.

5 Arguments

- | | |
|---|--------------|
| 1: nx – Integer | <i>Input</i> |
| <i>On entry:</i> the length of the time series, n . | |
| <i>Constraint:</i> $\mathbf{nx} \geq 1$. | |
| | |
| 2: mt_correction – NagMeanOrTrend | <i>Input</i> |
| <i>On entry:</i> whether the data are to be initially mean or trend corrected. | |
| $\mathbf{mt_correction} = \text{Nag_NoCorrection}$ for no correction, $\mathbf{mt_correction} = \text{Nag_Mean}$ for mean correction, $\mathbf{mt_correction} = \text{Nag_Trend}$ for trend correction. | |
| <i>Constraint:</i> $\mathbf{mt_correction} = \text{Nag_NoCorrection}$, Nag_Mean or Nag_Trend . | |
| | |
| 3: px – double | <i>Input</i> |
| <i>On entry:</i> the proportion of the data (totalled over both ends) to be initially tapered by the split cosine bell taper. (A value of 0.0 implies no tapering). | |
| <i>Constraint:</i> $0.0 \leq \mathbf{px} \leq 1.0$. | |
| | |
| 4: mw – Integer | <i>Input</i> |
| <i>On entry:</i> the value of M which determines the frequency width of the smoothing window as $2\pi/M$. A value of n implies no smoothing is to be carried out. | |
| <i>Constraint:</i> $1 \leq \mathbf{mw} \leq \mathbf{nx}$. | |
| | |
| 5: pw – double | <i>Input</i> |
| <i>On entry:</i> the shape argument, p , of the trapezium frequency window. | |

A value of 0.0 gives a triangular window, and a value of 1.0 a rectangular window.

If **mw** = **nx** (i.e., no smoothing is carried out), then **pw** is not used.

Constraint: $0.0 \leq \mathbf{pw} \leq 1.0$. if **mw** \neq **nx**.

6: **I** – Integer *Input*

On entry: the frequency division, L , of smoothed spectral estimates as $2\pi/L$.

Constraints:

$$\mathbf{I} \geq 1;$$

I must be a factor of **kc** (see below).

7: **kc** – Integer *Input*

On entry: the order of the fast Fourier transform (FFT), K , used to calculate the spectral estimates. **kc** should be a multiple of small primes such as 2^m where m is the smallest integer such that $2^m \geq 2n$, provided $m \leq 20$.

Constraints:

$$\mathbf{kc} \geq 2 \times \mathbf{nx};$$

kc must be a multiple of **I**. The largest prime factor of **kc** must not exceed 19, and the total number of prime factors of **kc**, counting repetitions, must not exceed 20. These two restrictions are imposed by the internal FFT algorithm used.

8: **lg_spect** – Nag_LoggedSpectra *Input*

On entry: indicates whether unlogged or logged spectral estimates and confidence limits are required. **lg_spect** = Nag_Unlogged for unlogged. **lg_spect** = Nag_Logged for logged.

Constraint: **lg_spect** = Nag_Unlogged or Nag_Logged.

9: **x[kc]** – const double *Input*

On entry: the n data points.

10: **g** – double ** *Output*

On exit: vector which contains the **ng** spectral estimates $\hat{f}(\omega_i)$, for $i = 0, 1, \dots, [L/2]$, in **g[0]** to **g[ng - 1]** (logged if **lg_spect** = Nag_Logged). The memory for this vector is allocated internally. If no memory is allocated to **g** (e.g., when an input error is detected) then **g** will be **NULL** on return. If repeated calls to this function are required then **NAG_FREE** should be used to free the memory in between calls.

11: **ng** – Integer * *Output*

On exit: the number of spectral estimates, $[L/2] + 1$, in **g**.

12: **stats[4]** – double *Output*

On exit: four associated statistics. These are the degrees of freedom in **stats[0]**, the lower and upper 95% confidence limit factors in **stats[1]** and **stats[2]** respectively (logged if **lg_spect** = Nag_Logged), and the bandwidth in **stats[3]**.

13: **fail** – NagError * *Input/Output*

The NAG error argument (see Section 3.6 in the Essential Introduction).

6 Error Indicators and Warnings

NE_2_INT_ARG_CONS

On entry, $\mathbf{kc} = \langle \text{value} \rangle$ while $\mathbf{l} = \langle \text{value} \rangle$. These arguments must satisfy $\mathbf{kc} \% \mathbf{l} = 0$ when $\mathbf{l} > 0$.

On entry, $\mathbf{kc} = \langle \text{value} \rangle$ while $\mathbf{nx} = \langle \text{value} \rangle$. These arguments must satisfy $\mathbf{kc} \geq 2 \times \mathbf{nx}$ when $\mathbf{nx} > 0$.

NE_2_INT_ARG_GT

On entry, $\mathbf{mw} = \langle \text{value} \rangle$ while $\mathbf{nx} = \langle \text{value} \rangle$. These arguments must satisfy $\mathbf{mw} \leq \mathbf{nx}$.

NE_ALLOC_FAIL

Dynamic memory allocation failed.

NE_BAD_PARAM

On entry, argument **lg_spect** had an illegal value.

On entry, argument **mt_correction** had an illegal value.

NE_CONFID_LIMIT_FACT

The calculation of confidence limit factors has failed. Spectral estimates (logged if requested) are returned in **g**, and degrees of freedom and bandwith in **stats**.

NE_FACTOR_GT

At least one of the prime factors of **kc** is greater than 19.

NE_INT_ARG_LT

On entry, $\mathbf{l} = \langle \text{value} \rangle$.

Constraint: $\mathbf{l} \geq 1$.

On entry, $\mathbf{mw} = \langle \text{value} \rangle$.

Constraint: $\mathbf{mw} \geq 1$.

On entry, $\mathbf{nx} = \langle \text{value} \rangle$.

Constraint: $\mathbf{nx} \geq 1$.

On entry, \mathbf{pw} must not be less than 0.0: $\mathbf{pw} = \langle \text{value} \rangle$.

NE_INTERNAL_ERROR

An internal error has occurred in this function. Check the function call and any array sizes. If the call is correct then please contact NAG for assistance.

NE_REAL_ARG_GT

On entry, \mathbf{pw} must not be greater than 1.0: $\mathbf{pw} = \langle \text{value} \rangle$.

On entry, \mathbf{px} must not be greater than 1.0: $\mathbf{px} = \langle \text{value} \rangle$.

NE_REAL_ARG_LT

On entry, \mathbf{px} must not be less than 0.0: $\mathbf{px} = \langle \text{value} \rangle$.

NE_SPECTRAL_ESTIM_NEG

One or more spectral estimates are negative. Unlogged spectral estimates are returned in **g** and the degrees of freedom, unlogged confidence limit factors and bandwith in **stats**.

NE_TOO_MANY_FACTORS

kc has more than 20 prime factors.

7 Accuracy

The FFT is a numerically stable process, and any errors introduced during the computation will normally be insignificant compared with uncertainty in the data.

8 Parallelism and Performance

Not applicable.

9 Further Comments

nag_tsa_spectrum_univar (g13cbc) carries out a FFT of length **kc** to calculate the sample spectrum. The time taken by the function for this is approximately proportional to **kc** $\times \log(\mathbf{kc})$ (but see Section 9 in nag_sum_fft_realherm_1d (c06pac) for further details).

10 Example

The example program reads a time series of length 131. It selects the mean correction option, a tapering proportion of 0.2, the option of no smoothing and a frequency division for logged spectral estimates of $2\pi/100$. It then calls nag_tsa_spectrum_univar (g13cbc) to calculate the univariate spectrum and prints the logged spectrum together with 95% confidence limits. The program then selects a smoothing window with frequency width $2\pi/30$ and shape argument 0.5 and recalculates and prints the logged spectrum and 95% confidence limits.
