nag_robust_corr_estim (g02hkc)

1 Purpose

nag_robust_corr_estim (g02hkc) computes a robust estimate of the covariance matrix for an expected fraction of gross errors.

2 Specification

```
#include <nag.h>
#include <nagg02.h>
void nag_robust_corr_estim (Integer n, Integer m, const double x[],
    Integer tdx, double eps, double cov[], double theta[], Integer max_iter,
    Integer print_iter, const char *outfile, double tol, Integer *iter,
    NagError *fail)
```

3 Description

For a set n observations on m variables in a matrix X , a robust estimate of the covariance matrix, C , and a robust estimate of location, θ , are given by:

$$C = \tau^2 (A^T A)^{-1}$$

where τ^2 is a correction factor and A is a lower triangular matrix found as the solution to the following equations.

$$z_i = A(x_i - \theta)$$

$$\frac{1}{n} \sum_{i=1}^n w(\|z_i\|_2) z_i = 0$$

and

$$\frac{1}{n} \sum_{i=1}^n u(\|z_i\|_2) z_i z_i^T - I = 0,$$

where x_i is a vector of length m containing the elements of the i th row of X ,

z_i is a vector of length m ,

I is the identity matrix and 0 is the zero matrix,

and w and u are suitable functions.

nag_robust_corr_estim (g02hkc) uses weight functions:

$$\begin{aligned} u(t) &= \frac{a_u}{t^2}, & \text{if } t < a_u^2 \\ u(t) &= 1, & \text{if } a_u^2 \leq t \leq b_u^2 \\ u(t) &= \frac{b_u}{t^2}, & \text{if } t > b_u^2 \end{aligned}$$

and

$$\begin{aligned} w(t) &= 1, & \text{if } t \leq c_w \\ w(t) &= \frac{c_w}{t}, & \text{if } t > c_w \end{aligned}$$

for constants a_u , b_u and c_w .

These functions solve a minimax problem considered by Huber (1981).

The values of a_u , b_u and c_w are calculated from the expected fraction of gross errors, ϵ (see Huber (1981) and Marazzi (1987)). The expected fraction of gross errors is the estimated proportion of outliers in the sample.

In order to make the estimate asymptotically unbiased under a Normal model a correction factor, τ^2 , is calculated, (see Huber (1981) and Marazzi (1987)).

Initial estimates of θ_j , for $j = 1, 2, \dots, m$, are given by the median of the j th column of X and the initial value of A is based on the median absolute deviation (see Marazzi (1987)). nag_robust_corr_estim (g02hkc) is based on routines in ROBETH, (see Marazzi (1987)).

5 Arguments

- | | | |
|----|--|---------------|
| 1: | n – Integer | <i>Input</i> |
| | <i>On entry:</i> the number of observations, n . | |
| | <i>Constraint:</i> $n > 1$. | |
| 2: | m – Integer | <i>Input</i> |
| | <i>On entry:</i> the number of columns of the matrix X , i.e., number of independent variables, m . | |
| | <i>Constraint:</i> $1 \leq m \leq n$. | |
| 3: | x [$\mathbf{n} \times \mathbf{tdx}$] – const double | <i>Input</i> |
| | <i>On entry:</i> $\mathbf{x}[(i-1) \times \mathbf{tdx} + j - 1]$ must contain the i th observation for the j th variable, for $i = 1, 2, \dots, n$ and $j = 1, 2, \dots, m$. | |
| 4: | tdx – Integer | <i>Input</i> |
| | <i>On entry:</i> the stride separating matrix column elements in the array x . | |
| | <i>Constraint:</i> $\mathbf{tdx} \geq m$. | |
| 5: | eps – double | <i>Input</i> |
| | <i>On entry:</i> the expected fraction of gross errors expected in the sample, ϵ . | |
| | <i>Constraint:</i> $0.0 \leq \mathbf{eps} < 1.0$. | |
| 6: | cov [$\mathbf{m} \times (\mathbf{m} + 1)/2$] – double | <i>Output</i> |
| | <i>On exit:</i> the $\mathbf{m} \times (\mathbf{m} + 1)/2$ elements of cov contain the upper triangular part of the covariance matrix. They are stored packed by column, i.e., C_{ij} , $j \geq i$, is stored in $\mathbf{cov}[j(j+1)/2 + i]$, for $i = 0, 1, \dots, \mathbf{m} - 1$ and $j = i, \dots, \mathbf{m} - 1$. | |
| 7: | theta [\mathbf{m}] – double | <i>Output</i> |
| | <i>On exit:</i> the robust estimate of the location arguments θ_j , for $j = 1, 2, \dots, m$. | |
| 8: | max_iter – Integer | <i>Input</i> |
| | <i>On entry:</i> the maximum number of iterations that will be used during the calculation of the covariance matrix. | |

Suggested value: **max_iter** = 150.

Constraint: **max_iter** > 0.

9: **print_iter** – Integer *Input*

On entry: indicates if the printing of information on the iterations is required and the rate at which printing is produced.

print_iter ≤ 0

No iteration monitoring is printed.

print_iter > 0

The value of A , θ and δ (see Section 9) will be printed at the first and every **print_iter** iterations.

10: **outfile** – const char * *Input*

On entry: a null terminated character string giving the name of the file to which results should be printed. If **outfile** is NULL or an empty string then the `stdout` stream is used. Note that the file will be opened in the append mode.

11: **tol** – double *Input*

On entry: the relative precision for the final estimates of the covariance matrix.

Constraint: **tol** > 0.0.

12: **iter** – Integer * *Output*

On exit: the number of iterations performed.

13: **fail** – NagError * *Input/Output*

The NAG error argument (see Section 2.7 in How to Use the NAG Library and its Documentation).

6 Error Indicators and Warnings

NE_2_INT_ARG_GT

On entry, **m** = $\langle \text{value} \rangle$ while **n** = $\langle \text{value} \rangle$. These arguments must satisfy **m** ≤ **n**.

NE_2_INT_ARG_LT

On entry, **tdx** = $\langle \text{value} \rangle$ while **m** = $\langle \text{value} \rangle$. These arguments must satisfy **tdx** ≥ **m**.

NE_ALLOC_FAIL

Dynamic memory allocation failed.

NE_C_ITER_UNSTABLE

The iterative procedure to find C has become unstable. This may happen if the value of **eps** is too large.

NE_CONST_COL

On entry, column $\langle \text{value} \rangle$ of array **x** has constant value.

NE_INT_ARG_LE

On entry, **max_iter** must not be less than or equal to 0: **max_iter** = $\langle \text{value} \rangle$.

NE_INT_ARG_LT

On entry, **m** = $\langle value \rangle$.

Constraint: **m** ≥ 1 .

On entry, **n** = $\langle value \rangle$.

Constraint: **n** ≥ 2 .

NE_NOT_APPEND_FILE

Cannot open file $\langle string \rangle$ for appending.

NE_NOT_CLOSE_FILE

Cannot close file $\langle string \rangle$.

NE_REAL_ARG_GE

On entry, **eps** must be not be greater than or equal to 1.0: **eps** = $\langle value \rangle$.

NE_REAL_ARG_LE

On entry, **tol** must not be less than or equal to 0.0: **tol** = $\langle value \rangle$.

NE_REAL_ARG_LT

On entry, **eps** must not be less than 0.0: **eps** = $\langle value \rangle$.

NE_TOO_MANY

Too many iterations($\langle value \rangle$).

The iterative procedure to find the co-variance matrix C , has failed to converge in **max_iter** iterations.

7 Accuracy

On successful exit the accuracy of the results is related to the value of **tol**, see Section 5. At an iteration let

- (i) $d1$ = the maximum value of the absolute relative change in A
- (ii) $d2$ = the maximum absolute change in $u(\|z_i\|_2)$
- (iii) $d3$ = the maximum absolute relative change in θ_j

and let $\delta = \max(d1, d2, d3)$. Then the iterative procedure is assumed to have converged when $\delta < \text{tol}$.

8 Parallelism and Performance

`nag_robust_corr_estim` (g02hkc) is not threaded in any implementation.

9 Further Comments

The existence of A , and hence c , will depend upon the function u , (see Marazzi (1987)), also if X is not of full rank a value of A will not be found. If the columns of X are almost linearly related, then convergence will be slow.

10 Example

A sample of 10 observations on three variables is read in and the robust estimate of the covariance matrix is computed assuming 10% gross errors are to be expected. The robust covariance is then printed.
