NAG Library Function Document

nag opt one var no deriv (e04abc)

1 Purpose

nag_opt_one_var_no_deriv (e04abc) searches for a minimum, in a given finite interval, of a continuous function of a single variable, using function values only. The method (based on quadratic interpolation) is intended for functions which have a continuous first derivative (although it will usually work if the derivative has occasional discontinuities).

2 Specification

```
#include <nag.h>
#include <nage04.h>

void nag_opt_one_var_no_deriv (
    void (*funct)(double xc, double *fc, Nag_Comm *comm),
    double e1, double e2, double *a, double *b, Integer max_fun, double *x, double *f, Nag_Comm *comm, NagError *fail)
```

3 Description

nag opt one var no deriv (e04abc) is applicable to problems of the form:

```
Minimize F(x) subject to a \le x \le b.
```

It normally computes a sequence of x values which tend in the limit to a minimum of F(x) subject to the given bounds. It also progressively reduces the interval [a, b] in which the minimum is known to lie. It uses the safeguarded quadratic-interpolation method described in Gill and Murray (1973).

You must supply a function **funct** to evaluate F(x). The arguments **e1** and **e2** together specify the accuracy

$$Tol(x) = \mathbf{e1} \times |x| + \mathbf{e2}$$

to which the position of the minimum is required. Note that **funct** is never called at any point which is closer than Tol(x) to a previous point.

If the original interval [a, b] contains more than one minimum, nag_opt_one_var_no_deriv (e04abc) will normally find one of the minima.

5 Arguments

1: **funct** – function, supplied by the user

External Function

funct must calculate the value of F(x) at any point x in [a, b].

```
The specification of funct is:

void funct (double xc, double *fc, Nag_Comm *comm)
```

Mark 26 e04abc.1

e04abc NAG Library Manual

1: \mathbf{xc} - double Input

On entry: x, the point at which the value of F(x) is required.

2: **fc** – double * Output

On exit: the value of the function F at the current point x.

3: **comm** – Nag Comm *

Pointer to structure of type Nag Comm; the following members are relevant to funct.

first - Nag Boolean Input

On entry: will be set to Nag_TRUE on the first call to **funct** and Nag_FALSE for all subsequent calls.

nf – Integer Input

On entry: the number of calls made to funct so far.

user – double *
iuser – Integer *
p – Pointer

The type Pointer will be void * with a C compiler that defines void * and char * otherwise. Before calling nag_opt_one_var_no_deriv (e04abc) these pointers may be allocated memory and initialized with various quantities for use by **funct** when called from nag opt one var no deriv (e04abc).

Note: **funct** should be tested separately before being used in conjunction with nag_opt_one_var no deriv (e04abc).

2: **e1** – double Input

On entry: the relative accuracy to which the position of a minimum is required. (Note that since e1 is a relative tolerance, the scaling of x is automatically taken into account.)

It is recommended that **e1** should be no smaller than 2ϵ , and preferably not much less than $\sqrt{\epsilon}$, where ϵ is the *machine precision*.

If **e1** is set to a value less than ϵ , its value is ignored and the default value of $\sqrt{\epsilon}$ is used instead. In particular, you may set **e1** = 0.0 to ensure that the default value is used.

3: **e2** – double Input

On entry: the absolute accuracy to which the position of a minimum is required. It is recommended that e^2 should be no smaller than 2ϵ .

If **e2** is set to a value less than ϵ , its value is ignored and the default value of $\sqrt{\epsilon}$ is used instead. In particular, you may set **e2** = 0.0 to ensure that the default value is used.

4: **a** – double * Input/Output

On entry: the lower bound a of the interval containing a minimum.

On exit: an improved lower bound on the position of the minimum.

5: \mathbf{b} - double * Input/Output

On entry: the upper bound b of the interval containing a minimum.

On exit: an improved upper bound on the position of the minimum.

Constraint: $\mathbf{b} > \mathbf{a} + \mathbf{e2}$.

e04abc.2 Mark 26

Note that the value $e2 = \sqrt{\epsilon}$ applies here if $e2 < \epsilon$ on entry to nag_opt_one_var_no_deriv (e04abc).

6: **max_fun** – Integer

Input

On entry: the maximum number of function evaluations (calls to **funct**) which you are prepared to allow.

The number of evaluations actually performed by nag_opt_one_var_no_deriv (e04abc) may be determined by supplying a non-NULL argument **comm** (see below) and examining the structure member **comm** \rightarrow **nf** on exit.

Constraint: $max_fun > 3$

(Few problems will require more than 30 function evaluations.)

7: \mathbf{x} – double *

On exit: the estimated position of the minimum.

8: **f** – double * Output

On exit: the value of F at the final point \mathbf{x} .

9: **comm** – Nag Comm *

Input/Output

Note: **comm** is a NAG defined type (see Section 2.3.1.1 in How to Use the NAG Library and its Documentation).

On entry/exit: structure containing pointers for communication to user-supplied functions; see the above description of **funct** for details. The number of times the function **funct** was called is returned in the member **comm** \rightarrow **nf**.

If you do not need to make use of this communication feature, the null pointer NAGCOMM_NULL may be used in the call to nag_opt_one_var_no_deriv (e04abc); **comm** will then be declared internally for use in calls to user-supplied functions.

10: **fail** - NagError *

Input/Output

The NAG error argument (see Section 2.7 in How to Use the NAG Library and its Documentation).

6 Error Indicators and Warnings

NE 2 REAL ARG GE

On entry, $\mathbf{a} + \mathbf{e2} = \langle value \rangle$ while $\mathbf{b} = \langle value \rangle$. These arguments must satisfy $\mathbf{a} + \mathbf{e2} < \mathbf{b}$.

NE_INT_ARG_LT

On entry, max_fun must not be less than 3: $max_fun = \langle value \rangle$.

NW MAX FUN

The maximum number of function calls, \(\frac{value}{\} \), have been performed.

This may have happened simply because **max_fun** was set too small for a particular problem, or may be due to a mistake in the user-supplied function, **funct**. If no mistake can be found in **funct**, restart nag_opt_one_var_no_deriv (e04abc) (preferably with the values of **a** and **b** given on exit from the previous call to nag opt one var no deriv (e04abc)).

NAG Library Manual

7 Accuracy

If F(x) is δ -unimodal for some $\delta < Tol(x)$, where $Tol(x) = \mathbf{e1} \times |x| + \mathbf{e2}$, then, on exit, x approximates the minimum of F(x) in the original interval [a,b] with an error less than $3 \times Tol(x)$.

8 Parallelism and Performance

nag_opt_one_var_no_deriv (e04abc) is not threaded in any implementation.

9 Further Comments

Timing depends on the behaviour of F(x), the accuracy demanded, and the length of the interval [a,b]. Unless F(x) can be evaluated very quickly, the run time will usually be dominated by the time spent in **funct**.

If F(x) has more than one minimum in the original interval [a, b], nag_opt_one_var_no_deriv (e04abc) will determine an approximation x (and improved bounds a and b) for one of the minima.

If nag_opt_one_var_no_deriv (e04abc) finds an x such that $F(x-\delta_1) > F(x) < F(x+\delta_2)$ for some $\delta_1, \delta_2 \geq Tol(x)$, the interval $[x-\delta_1, x+\delta_2]$ will be regarded as containing a minimum, even if F(x) is less than $F(x-\delta_1)$ and $F(x+\delta_2)$ only due to rounding errors in the user-supplied function. Therefore funct should be programmed to calculate F(x) as accurately as possible, so that nag_opt_one_var_no_deriv (e04abc) will not be liable to find a spurious minimum.

10 Example

A sketch of the function

$$F(x) = \frac{\sin x}{x}$$

shows that it has a minimum somewhere in the range [3.5, 5.0]. The example program below shows how nag_opt_one_var_no_deriv (e04abc) can be used to obtain a good approximation to the position of a minimum.
