

NAG Library Function Document

nag_censored_normal (g07bbc)

1 Purpose

nag_censored_normal (g07bbc) computes maximum likelihood estimates and their standard errors for arguments of the Normal distribution from grouped and/or censored data.

2 Specification

```
#include <nag.h>
#include <nagg07.h>

void nag_censored_normal (Nag_CEMethod method, Integer n, const double x[],
    const double xc[], const Integer ic[], double *xmu, double *xsig,
    double tol, Integer maxit, double *sexmu, double *sexsig, double *corr,
    double *dev, Integer nobst[], Integer *nit, NagError *fail)
```

3 Description

A sample of size n is taken from a Normal distribution with mean μ and variance σ^2 and consists of grouped and/or censored data. Each of the n observations is known by a pair of values (L_i, U_i) such that:

$$L_i \leq x_i \leq U_i.$$

The data is represented as particular cases of this form:

exactly specified observations occur when $L_i = U_i = x_i$,

right-censored observations, known only by a lower bound, occur when $U_i \rightarrow \infty$,

left-censored observations, known only by an upper bound, occur when $L_i \rightarrow -\infty$,

and interval-censored observations when $L_i < x_i < U_i$.

Let the set A identify the exactly specified observations, sets B and C identify the observations censored on the right and left respectively, and set D identify the observations confined between two finite limits. Also let there be r exactly specified observations, i.e., the number in A . The probability density function for the standard Normal distribution is

$$Z(x) = \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{1}{2}x^2\right), \quad -\infty < x < \infty$$

and the cumulative distribution function is

$$P(X) = 1 - Q(X) = \int_{-\infty}^X Z(x) dx.$$

The log-likelihood of the sample can be written as:

$$L(\mu, \sigma) = -r \log \sigma - \frac{1}{2} \sum_A \{(x_i - \mu)/\sigma\}^2 + \sum_B \log(Q(l_i)) + \sum_C \log(P(u_i)) + \sum_D \log(p_i)$$

where $p_i = P(u_i) - P(l_i)$ and $u_i = (U_i - \mu)/\sigma$, $l_i = (L_i - \mu)/\sigma$.

Let

$$S(x_i) = \frac{Z(x_i)}{Q(x_i)}, \quad S_1(l_i, u_i) = \frac{Z(l_i) - Z(u_i)}{p_i}$$

and

$$S_2(l_i, u_i) = \frac{u_i Z(u_i) - l_i Z(l_i)}{p_i},$$

then the first derivatives of the log-likelihood can be written as:

$$\frac{\partial L(\mu, \sigma)}{\partial \mu} = L_1(\mu, \sigma) = \sigma^{-2} \sum_A (x_i - \mu) + \sigma^{-1} \sum_B S(l_i) - \sigma^{-1} \sum_C S(-u_i) + \sigma^{-1} \sum_D S_1(l_i, u_i)$$

and

$$\begin{aligned} \frac{\partial L(\mu, \sigma)}{\partial \sigma} = L_2(\mu, \sigma) = & -r\sigma^{-1} + \sigma^{-3} \sum_A (x_i - \mu)^2 + \sigma^{-1} \sum_B l_i S(l_i) - \sigma^{-1} \sum_C u_i S(-u_i) \\ & - \sigma^{-1} \sum_D S_2(l_i, u_i) \end{aligned}$$

The maximum likelihood estimates, $\hat{\mu}$ and $\hat{\sigma}$, are the solution to the equations:

$$L_1(\hat{\mu}, \hat{\sigma}) = 0 \quad (1)$$

and

$$L_2(\hat{\mu}, \hat{\sigma}) = 0 \quad (2)$$

and if the second derivatives $\frac{\partial^2 L}{\partial^2 \mu}$, $\frac{\partial^2 L}{\partial \mu \partial \sigma}$ and $\frac{\partial^2 L}{\partial^2 \sigma}$ are denoted by L_{11} , L_{12} and L_{22} respectively, then estimates of the standard errors of $\hat{\mu}$ and $\hat{\sigma}$ are given by:

$$\text{se}(\hat{\mu}) = \sqrt{\frac{-L_{22}}{L_{11}L_{22} - L_{12}^2}}, \quad \text{se}(\hat{\sigma}) = \sqrt{\frac{-L_{11}}{L_{11}L_{22} - L_{12}^2}}$$

and an estimate of the correlation of $\hat{\mu}$ and $\hat{\sigma}$ is given by:

$$\frac{L_{12}}{\sqrt{L_{11}L_{22}}}$$

To obtain the maximum likelihood estimates the equations (1) and (2) can be solved using either the Newton–Raphson method or the Expectation-maximization (*EM*) algorithm of Dempster *et al.* (1977).

Newton–Raphson Method

This consists of using approximate estimates $\tilde{\mu}$ and $\tilde{\sigma}$ to obtain improved estimates $\tilde{\mu} + \delta\tilde{\mu}$ and $\tilde{\sigma} + \delta\tilde{\sigma}$ by solving

$$\delta\tilde{\mu}L_{11} + \delta\tilde{\sigma}L_{12} + L_1 = 0,$$

$$\delta\tilde{\mu}L_{12} + \delta\tilde{\sigma}L_{22} + L_2 = 0,$$

for the corrections $\delta\tilde{\mu}$ and $\delta\tilde{\sigma}$.

EM Algorithm

The expectation step consists of constructing the variable w_i as follows:

$$\text{if } i \in A, \quad w_i = x_i \quad (3)$$

$$\text{if } i \in B, \quad w_i = E(x_i | x_i > L_i) = \mu + \sigma S(l_i) \quad (4)$$

$$\text{if } i \in C, \quad w_i = E(x_i | x_i < U_i) = \mu - \sigma S(-u_i) \quad (5)$$

$$\text{if } i \in D, \quad w_i = E(x_i | L_i < x_i < U_i) = \mu + \sigma S_1(l_i, u_i) \quad (6)$$

the maximization step consists of substituting (3), (4), (5) and (6) into (1) and (2) giving:

$$\hat{\mu} = \sum_{i=1}^n \hat{w}_i / n \quad (7)$$

and

$$\hat{\sigma}^2 = \sum_{i=1}^n (\hat{w}_i - \hat{\mu})^2 / \left\{ r + \sum_B T(\hat{l}_i) + \sum_C T(-\hat{u}_i) + \sum_D T_1(\hat{l}_i, \hat{u}_i) \right\} \quad (8)$$

where

$$T(x) = S(x)\{S(x) - x\}, \quad T_1(l, u) = S_1^2(l, u) + S_2(l, u)$$

and where \hat{w}_i , \hat{l}_i and \hat{u}_i are w_i , l_i and u_i evaluated at $\hat{\mu}$ and $\hat{\sigma}$. Equations (3) to (8) are the basis of the *EM* iterative procedure for finding $\hat{\mu}$ and $\hat{\sigma}^2$. The procedure consists of alternately estimating $\hat{\mu}$ and $\hat{\sigma}^2$ using (7) and (8) and estimating $\{\hat{w}_i\}$ using (3) to (6).

In choosing between the two methods a general rule is that the Newton–Raphson method converges more quickly but requires good initial estimates whereas the *EM* algorithm converges slowly but is robust to the initial values. In the case of the censored Normal distribution, if only a small proportion of the observations are censored then estimates based on the exact observations should give good enough initial estimates for the Newton–Raphson method to be used. If there are a high proportion of censored observations then the *EM* algorithm should be used and if high accuracy is required the subsequent use of the Newton–Raphson method to refine the estimates obtained from the *EM* algorithm should be considered.

5 Arguments

- 1: **method** – Nag_CEMethod *Input*
On entry: indicates whether the Newton–Raphson or *EM* algorithm should be used.
 If **method** = Nag_CE_NR, then the Newton–Raphson algorithm is used.
 If **method** = Nag_CE_EM, then the *EM* algorithm is used.
Constraint: **method** = Nag_CE_NR or Nag_CE_EM.
- 2: **n** – Integer *Input*
On entry: n , the number of observations.
Constraint: $n \geq 2$.
- 3: **x[n]** – const double *Input*
On entry: the observations x_i , L_i or U_i , for $i = 1, 2, \dots, n$.
 If the observation is exactly specified – the exact value, x_i .
 If the observation is right-censored – the lower value, L_i .
 If the observation is left-censored – the upper value, U_i .
 If the observation is interval-censored – the lower or upper value, L_i or U_i , (see **xc**).

- 4: **xc[n]** – const double *Input*
On entry: if the j th observation, for $j = 1, 2, \dots, n$ is an interval-censored observation then **xc**[$j - 1$] should contain the complementary value to **x**[$j - 1$], that is, if **x**[$j - 1$] < **xc**[$j - 1$], then **xc**[$j - 1$] contains upper value, U_i , and if **x**[$j - 1$] > **xc**[$j - 1$], then **xc**[$j - 1$] contains lower value, L_i . Otherwise if the j th observation is exact or right- or left-censored **xc**[$j - 1$] need not be set.
Note: if **x**[$j - 1$] = **xc**[$j - 1$] then the observation is ignored.
- 5: **ic[n]** – const Integer *Input*
On entry: **ic**[$i - 1$] contains the censoring codes for the i th observation, for $i = 1, 2, \dots, n$.
 If **ic**[$i - 1$] = 0, the observation is exactly specified.
 If **ic**[$i - 1$] = 1, the observation is right-censored.
 If **ic**[$i - 1$] = 2, the observation is left-censored.
 If **ic**[$i - 1$] = 3, the observation is interval-censored.
Constraint: **ic**[$i - 1$] = 0, 1, 2 or 3, for $i = 1, 2, \dots, n$.
- 6: **xmu** – double * *Input/Output*
On entry: if **xsig** > 0.0 the initial estimate of the mean, μ ; otherwise **xmu** need not be set.
On exit: the maximum likelihood estimate, $\hat{\mu}$, of μ .
- 7: **xsig** – double * *Input/Output*
On entry: specifies whether an initial estimate of μ and σ are to be supplied.
xsig > 0.0
xsig is the initial estimate of σ and **xmu** must contain an initial estimate of μ .
xsig ≤ 0.0
 Initial estimates of **xmu** and **xsig** are calculated internally from:
 (a) the exact observations, if the number of exactly specified observations is ≥ 2 ; or
 (b) the interval-censored observations; if the number of interval-censored observations is ≥ 1 ; or
 (c) they are set to 0.0 and 1.0 respectively.
On exit: the maximum likelihood estimate, $\hat{\sigma}$, of σ .
- 8: **tol** – double *Input*
On entry: the relative precision required for the final estimates of μ and σ . Convergence is assumed when the absolute relative changes in the estimates of both μ and σ are less than **tol**.
 If **tol** = 0.0, then a relative precision of 0.000005 is used.
Constraint: **machine precision** < **tol** ≤ 1.0 or **tol** = 0.0.
- 9: **maxit** – Integer *Input*
On entry: the maximum number of iterations.
 If **maxit** ≤ 0, then a value of 25 is used.
- 10: **sexmu** – double * *Output*
On exit: the estimate of the standard error of $\hat{\mu}$.

- 11: **sexsig** – double * *Output*
On exit: the estimate of the standard error of $\hat{\sigma}$.
- 12: **corr** – double * *Output*
On exit: the estimate of the correlation between $\hat{\mu}$ and $\hat{\sigma}$.
- 13: **dev** – double * *Output*
On exit: the maximized log-likelihood, $L(\hat{\mu}, \hat{\sigma})$.
- 14: **nobs[4]** – Integer *Output*
On exit: the number of the different types of each observation;
nobs[0] contains number of right-censored observations.
nobs[1] contains number of left-censored observations.
nobs[2] contains number of interval-censored observations.
nobs[3] contains number of exactly specified observations.
- 15: **nit** – Integer * *Output*
On exit: the number of iterations performed.
- 16: **fail** – NagError * *Input/Output*
The NAG error argument (see Section 2.7 in How to Use the NAG Library and its Documentation).

6 Error Indicators and Warnings

NE_ALLOC_FAIL

Dynamic memory allocation failed.

See Section 2.3.1.2 in How to Use the NAG Library and its Documentation for further information.

NE_BAD_PARAM

On entry, argument $\langle value \rangle$ had an illegal value.

NE_CONVERGENCE

Method has not converged in $\langle value \rangle$ iterations.

NE_DIVERGENCE

Process has diverged.

NE_EM_PROCESS

The EM process has failed.

NE_INT

On entry, $\mathbf{n} = \langle value \rangle$.

Constraint: $\mathbf{n} \geq 2$.

NE_INT_ARRAY

On entry, $\mathbf{ic}[\langle value \rangle]$ is invalid, it contains $\langle value \rangle$.

NE_INTERNAL_ERROR

An internal error has occurred in this function. Check the function call and any array sizes. If the call is correct then please contact NAG for assistance.

An unexpected error has been triggered by this function. Please contact NAG.
See Section 2.7.6 in How to Use the NAG Library and its Documentation for further information.

NE_NO_LICENCE

Your licence key may have expired or may not have been installed correctly.
See Section 2.7.5 in How to Use the NAG Library and its Documentation for further information.

NE_OBSERVATIONS

On entry, effective number of observations < 2 .

NE_REAL

On entry, **tol** is invalid: **tol** = $\langle value \rangle$.

NE_STANDARD_ERRORS

Standard errors cannot be computed.

7 Accuracy

The accuracy is controlled by the argument **tol**.

If high precision is requested with the *EM* algorithm then there is a possibility that, due to the slow convergence, before the correct solution has been reached the increments of $\hat{\mu}$ and $\hat{\sigma}$ may be smaller than **tol** and the process will prematurely assume convergence.

8 Parallelism and Performance

nag_censored_normal (g07bbc) is not threaded in any implementation.

9 Further Comments

The process is deemed divergent if three successive increments of μ or σ increase.

10 Example

A sample of 18 observations and their censoring codes are read in and the Newton–Raphson method used to compute the estimates.
