

X04BGFP

NAG Parallel Library Routine Document

Note: before using this routine, please read the Users' Note for your implementation to check for implementation-dependent details. You are advised to enclose any calls to NAG Parallel Library routines between calls to Z01AAFP and Z01ABFP.

1 Description

X04BGFP reads an m by n real matrix A from an external file (stored in its natural, non-distributed form) into an array in a cyclic two-dimensional block distribution on a logical grid of processors.

This routine distributes matrices in the form required by some routines in Chapter F04.

2 Specification

```
SUBROUTINE X04BGFP(ICNTXT, NIN, M, N, NB, A, LDA, IFAIL)
DOUBLE PRECISION  A(LDA,*)
INTEGER           ICNTXT, NIN, M, N, NB, LDA, IFAIL
```

3 Usage

3.1 Definitions

The following definitions are used in describing the data distribution within this document:

- m_p – the number of rows in the Library Grid.
- n_p – the number of columns in the Library Grid.
- p_r – the row grid coordinate of the calling processor.
- p_c – the column grid coordinate of the calling processor.
- N_b – the blocking factor for the distribution of the rows and columns of a matrix X .
- $\text{numroc}(\alpha, b_\ell, q, s, k)$ – a function which gives the **number of rows or columns** of a distributed matrix owned by the processor with the row or column coordinate q (p_r or p_c), where α is the total number of rows or columns of the matrix, b_ℓ is the blocking factor used (N_b), s is the row or column coordinate of the processor that possesses the first row or column of the distributed matrix and k is either n_p or m_p . The Library provides the function Z01CAFP (NUMROC) for the evaluation of this function.

3.2 Global and Local Arguments

The following global **input** arguments must have the same value on entry to the routine on each processor and the global **output** arguments will have the same value on exit from the routine on each processor:

Global input arguments: M, N, NB, IFAIL

Global output arguments: IFAIL

Note: NIN may have a different value on each processor but it is likely to be the same on each processor – the only constraint is that it must be attached to the same file (or identical files) on each processor.

3.3 Distribution Strategy

The cyclic block data distribution is described in more detail in the Essential Introduction of the NAG Parallel Library and in the F04 Chapter Introduction.

4 Arguments

- 1:** ICNTXT — INTEGER *Local Input*
On entry: the Library context, usually returned by a call to the Library Grid initialisation routine Z01AAFP.
Note: the value of ICNTXT **must not** be changed.
- 2:** NIN — INTEGER *Local Input*
On entry: the unit number on which the external file is to be read.
Constraint: $0 \leq \text{NIN} \leq 99$.
- 3:** M — INTEGER *Global Input*
On entry: m , the number of rows of the matrix A .
Constraint: $M \geq 0$.
- 4:** N — INTEGER *Global Input*
On entry: n , the number of columns of the matrix A .
Constraint: $N \geq 0$.
- 5:** NB — INTEGER *Global Input*
On entry: N_b , the blocking factor for distributing the matrix A .
Constraint: $\text{NB} \geq 1$.
- 6:** A(LDA,*) — DOUBLE PRECISION array *Local Output*
Note: the size of the second dimension of the array A must be at least $\max(1, \text{numroc}(N, \text{NB}, p_c, 0, n_p))$.
On exit: the local part of the matrix A , distributed in a cyclic two-dimensional block fashion.
- 7:** LDA — INTEGER *Local Input*
On entry: the size of the first dimension of the array A as declared in the (sub)program from which X04BGFP is called.
Constraint: $\text{LDA} \geq \max(1, \text{numroc}(M, \text{NB}, p_r, 0, m_p))$
- 8:** IFAIL — INTEGER *Global Input/Global Output*
The NAG Parallel Library provides a mechanism, via the routine Z02EAFP, to reduce the amount of parameter validation performed by this routine. For a full description refer to the Z02 Chapter Introduction.
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this argument (described in the Essential Introduction) the recommended values are:
IFAIL = 0, if multigridding is **not** employed;
IFAIL = -1, if multigridding is employed.
On exit: IFAIL = 0 (or -9999 if reduced error checking is enabled) unless the routine detects an error (see Section 5).

5 Errors and Warnings

If on entry $IFAIL = 0$ or -1 , explanatory error messages are output from the root processor (or processor $\{0,0\}$ when the root processor is not available) on the current error message unit (as defined by X04AAF).

5.1 Full Error Checking Mode Only

$IFAIL = -2000$

The routine has been called with an invalid value of $ICNTXT$ on one or more processors.

$IFAIL = -1000$

The logical processor grid and library mechanism (Library Grid) have not been correctly defined, see Z01AAFP.

$IFAIL = -i$

On entry, the i th argument was invalid. This error occurred either because a global argument did not have the same value on all logical processors, or because its value on one or more processors was incorrect. An explanatory message distinguishes between these two cases.

5.2 Any Error Checking Mode

$IFAIL = 1$

The routine has reached the end of the external file unexpectedly. This is probably due to supplying values for M and N which are too large for the amount of data actually stored in the file.

$IFAIL = 2$

An error has occurred while reading the data, probably due to the routine trying to read an incorrect data type. This may occur if there are non-numerical characters accidentally mixed with the matrix data or if the current read position is not at the beginning of the matrix data when the routine is called.

6 Further Comments

All of the processors read from the data file concurrently. On exit from the routine all processors will have read data to the same point in the file. There is no way of checking that the data file is the same for all processors; if the file is not the same for all processors, the behaviour of the routine could be unpredictable.

The routine reads exactly N matrix elements for each row of A and assumes that the next row of A begins on the next line of the external file.

7 References

None.

8 Example

This example reads in a matrix A and the right-hand side B of a system of equations $AX = B$ from a data file, computes the solution of the system of equations X using routine F04EBFP and prints the solution to standard output. The example uses a 2 by 2 logical processor grid and a 2 by 2 block.

Note: the listing of the Example Program presented below does not give a full pathname for the data file being opened, but in general the user must give the full pathname in this and any other OPEN statement.
