NAG Library Routine Document F08BHF (DTZRZF)

Note: before using this routine, please read the Users' Note for your implementation to check the interpretation of **bold italicised** terms and other implementation-dependent details.

1 Purpose

F08BHF (DTZRZF) reduces the m by n ($m \le n$) real upper trapezoidal matrix A to upper triangular form by means of orthogonal transformations.

2 Specification

SUBROUTINE FO8BHF (M, N, A, LDA, TAU, WORK, LWORK, INFO)

INTEGER

M, N, LDA, LWORK, INFO

REAL (KIND=nag_wp) A(LDA,*), TAU(*), WORK(max(1,LWORK))

The routine may be called by its LAPACK name dtzrzf.

3 Description

The m by $n \ (m \le n)$ real upper trapezoidal matrix A given by

$$A = (R_1 \quad R_2),$$

where R_1 is an m by m upper triangular matrix and R_2 is an m by (n-m) matrix, is factorized as

$$A = (R \quad 0)Z,$$

where R is also an m by m upper triangular matrix and Z is an n by n orthogonal matrix.

4 References

5 Parameters

1: M – INTEGER Input

On entry: m, the number of rows of the matrix A.

Constraint: $M \ge 0$.

2: N – INTEGER Input

On entry: n, the number of columns of the matrix A.

Constraint: $N \ge 0$.

3: A(LDA,*) - REAL (KIND=nag wp) array

Input/Output

Note: the second dimension of the array A must be at least max(1, N).

On entry: the leading m by n upper trapezoidal part of the array A must contain the matrix to be factorized.

Mark 24 F08BHF.1

F08BHF NAG Library Manual

On exit: the leading m by m upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first m rows of A, with the array TAU, represent the orthogonal matrix Z as a product of m elementary reflectors (see Section 3.3.6 in the F08 Chapter Introduction).

4: LDA – INTEGER Input

On entry: the first dimension of the array A as declared in the (sub)program from which F08BHF (DTZRZF) is called.

Constraint: LDA $\geq \max(1, M)$.

5: TAU(*) - REAL (KIND=nag_wp) array

Output

Note: the dimension of the array TAU must be at least max(1, M).

On exit: the scalar factors of the elementary reflectors.

6: WORK(max(1, LWORK)) - REAL (KIND=nag wp) array

Workspace

On exit: if INFO = 0, WORK(1) contains the minimum value of LWORK required for optimal performance.

7: LWORK – INTEGER

Input

On entry: the dimension of the array WORK as declared in the (sub)program from which F08BHF (DTZRZF) is called.

If LWORK = -1, a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued.

Suggested value: for optimal performance, LWORK \geq M \times nb, where nb is the optimal **block size**. Constraint: LWORK \geq max(1, M) or LWORK = -1.

8: INFO – INTEGER

Output

On exit: INFO = 0 unless the routine detects an error (see Section 6).

6 Error Indicators and Warnings

Errors or warnings detected by the routine:

INFO < 0

If INFO = -i, argument i had an illegal value. An explanatory message is output, and execution of the program is terminated.

7 Accuracy

The computed factorization is the exact factorization of a nearby matrix A + E, where

$$||E||_2 = O\epsilon ||A||_2$$

and ϵ is the *machine precision*.

8 Further Comments

The total number of floating point operations is approximately $4m^2(n-m)$.

The complex analogue of this routine is F08BVF (ZTZRZF).

F08BHF.2 Mark 24

9 Example

This example solves the linear least squares problems

$$\min_{x} \left\| b_j - Ax_j \right\|_2, \qquad j = 1, 2$$

for the minimum norm solutions x_1 and x_2 , where b_i is the jth column of the matrix B,

$$A = \begin{pmatrix} -0.09 & 0.14 & -0.46 & 0.68 & 1.29 \\ -1.56 & 0.20 & 0.29 & 1.09 & 0.51 \\ -1.48 & -0.43 & 0.89 & -0.71 & -0.96 \\ -1.09 & 0.84 & 0.77 & 2.11 & -1.27 \\ 0.08 & 0.55 & -1.13 & 0.14 & 1.74 \\ -1.59 & -0.72 & 1.06 & 1.24 & 0.34 \end{pmatrix} \quad \text{and} \quad B = \begin{pmatrix} 7.4 & 2.7 \\ 4.2 & -3.0 \\ -8.3 & -9.6 \\ 1.8 & 1.1 \\ 8.6 & 4.0 \\ 2.1 & -5.7 \end{pmatrix}.$$

The solution is obtained by first obtaining a QR factorization with column pivoting of the matrix A, and then the RZ factorization of the leading k by k part of R is computed, where k is the estimated rank of A. A tolerance of 0.01 is used to estimate the rank of A from the upper triangular factor, R.

Note that the block size (NB) of 64 assumed in this example is not realistic for such a small problem, but should be suitable for large problems.
