NAG Library Routine Document

G03ADF

Note: before using this routine, please read the Users' Note for your implementation to check the interpretation of **bold italicised** terms and other implementation-dependent details.

1 Purpose

G03ADF performs canonical correlation analysis upon input data matrices.

2 Specification

```
SUBROUTINE GO3ADF (WEIGHT, N, M, Z, LDZ, ISZ, NX, NY, WT, E, LDE, NCV, CVX, LDCVX, MCV, CVY, LDCVY, TOL, WK, IWK, IFAIL)

INTEGER

N, M, LDZ, ISZ(M), NX, NY, LDE, NCV, LDCVX, MCV, LDCVY, WK, IFAIL

REAL (KIND=nag_wp) Z(LDZ,M), WT(*), E(LDE,6), CVX(LDCVX,MCV), CVY(LDCVY,MCV), TOL, WK(IWK)

CHARACTER(1) WEIGHT
```

3 Description

Let there be two sets of variables, x and y. For a sample of n observations on n_x variables in a data matrix X and n_y variables in a data matrix Y, canonical correlation analysis seeks to find a small number of linear combinations of each set of variables in order to explain or summarise the relationships between them. The variables thus formed are known as canonical variates.

Let the variance-covariance matrix of the two datasets be

$$\begin{pmatrix} S_{xx} & S_{xy} \\ S_{yx} & S_{yy} \end{pmatrix}$$

and let

$$\Sigma = S_{yy}^{-1} S_{yx} S_{xx}^{-1} S_{xy}$$

then the canonical correlations can be calculated from the eigenvalues of the matrix Σ . However, G03ADF calculates the canonical correlations by means of a singular value decomposition (SVD) of a matrix V. If the rank of the data matrix X is k_x and the rank of the data matrix Y is k_y , and both X and Y have had variable (column) means subtracted then the k_x by k_y matrix V is given by:

$$V = Q_x^{\mathsf{T}} Q_y,$$

where Q_x is the first k_x columns of the orthogonal matrix Q either from the QR decomposition of X if X is of full column rank, i.e., $k_x = n_x$:

$$X = Q_x R_x$$

or from the SVD of X if $k_x < n_x$:

$$X = Q_x D_x P_x^{\mathsf{T}}.$$

Similarly Q_y is the first k_y columns of the orthogonal matrix Q either from the QR decomposition of Y if Y is of full column rank, i.e., $k_y = n_y$:

$$Y = Q_y R_y$$

or from the SVD of Y if $k_y < n_y$:

$$Y = Q_y D_y P_y^{\mathsf{T}}.$$

Let the SVD of V be:

$$V = U_x \Delta U_y^{\mathrm{T}}$$

then the nonzero elements of the diagonal matrix Δ , δ_i , for i = 1, 2, ..., l, are the l canonical correlations associated with the l canonical variates, where $l = \min(k_x, k_y)$.

The eigenvalues, λ_i^2 , of the matrix Σ are given by:

$$\lambda_i^2 = \delta_i^2$$
.

The value of $\pi_i = \lambda_i^2 / \sum \lambda_i^2$ gives the proportion of variation explained by the *i*th canonical variate. The values of the π_i 's give an indication as to how many canonical variates are needed to adequately describe the data, i.e., the dimensionality of the problem.

To test for a significant dimensionality greater than i the χ^2 statistic:

$$\left(n-rac{1}{2}(k_x+k_y+3)
ight)\sum_{j=i+1}^l\logig(1-\delta_j^2ig)$$

can be used. This is asymptotically distributed as a χ^2 -distribution with $(k_x - i)(k_y - i)$ degrees of freedom. If the test for $i = k_{\min}$ is not significant, then the remaining tests for $i > k_{\min}$ should be ignored.

The loadings for the canonical variates are calculated from the matrices U_x and U_y respectively. These matrices are scaled so that the canonical variates have unit variance.

5 Parameters

1: WEIGHT – CHARACTER(1)

Input

On entry: indicates if weights are to be used.

WEIGHT = 'U'

No weights are used.

WEIGHT = 'W'

Weights are used and must be supplied in WT.

Constraint: WEIGHT = 'U' or 'W'.

2: N - INTEGER

Input

On entry: n, the number of observations.

Constraint: N > NX + NY.

3: M - INTEGER

Input

On entry: m, the total number of variables.

Constraint: $M \ge NX + NY$.

4: $Z(LDZ,M) - REAL (KIND=nag_wp) array$

Input

On entry: Z(i, j) must contain the *i*th observation for the *j*th variable, for i = 1, 2, ..., n and j = 1, 2, ..., m.

G03ADF.2 Mark 24

G03ADF

Both x and y variables are to be included in Z, the indicator array, ISZ, being used to assign the variables in Z to the x or y sets as appropriate.

5: LDZ – INTEGER Input

On entry: the first dimension of the array Z as declared in the (sub)program from which G03ADF is called.

Constraint: $LDZ \ge N$.

6: ISZ(M) – INTEGER array

Input

On entry: ISZ(j) indicates whether or not the jth variable is included in the analysis and to which set of variables it belongs.

ISZ(j) > 0

The variable contained in the jth column of Z is included as an x variable in the analysis.

ISZ(j) < 0

The variable contained in the jth column of Z is included as a y variable in the analysis.

ISZ(j) = 0

The variable contained in the jth column of Z is not included in the analysis.

Constraint: only NX elements of ISZ can be > 0 and only NY elements of ISZ can be < 0.

7: NX – INTEGER Input

On entry: the number of x variables in the analysis, n_x .

Constraint: $NX \ge 1$.

8: NY – INTEGER Input

On entry: the number of y variables in the analysis, n_y .

Constraint: $NY \ge 1$.

9: $WT(*) - REAL (KIND=nag_wp) array$

Input

Note: the dimension of the array WT must be at least N if WEIGHT = 'W', and at least 1 otherwise.

On entry: if WEIGHT = 'W', the first n elements of WT must contain the weights to be used in the analysis.

If WT(i) = 0.0, the *i*th observation is not included in the analysis. The effective number of observations is the sum of weights.

If WEIGHT = 'U', WT is not referenced and the effective number of observations is n.

Constraints:

$$WT(i) \ge 0.0$$
, for $i = 1, 2, ..., n$;
the sum of weights $\ge NX + NY + 1$.

10: E(LDE,6) – REAL (KIND=nag wp) array

Output

On exit: the statistics of the canonical variate analysis.

E(i,1)

The canonical correlations, δ_i , for i = 1, 2, ..., l.

E(i,2)

The eigenvalues of Σ , λ_i^2 , for i = 1, 2, ..., l.

E(i,3)

The proportion of variation explained by the ith canonical variate, for $i=1,2,\ldots,l$.

G03ADF NAG Library Manual

E(i,4)The χ^2 statistic for the *i*th canonical variate, for $i=1,2,\ldots,l$.

E(i,5)

The degrees of freedom for χ^2 statistic for the *i*th canonical variate, for i = 1, 2, ..., l.

E(i,6)

The significance level for the χ^2 statistic for the *i*th canonical variate, for i = 1, 2, ..., l.

11: LDE – INTEGER

Input

On entry: the first dimension of the array E as declared in the (sub)program from which G03ADF is called.

Constraint: LDE $\geq \min(NX, NY)$.

12: NCV – INTEGER

Output

On exit: the number of canonical correlations, l. This will be the minimum of the rank of X and the rank of Y.

13: CVX(LDCVX,MCV) - REAL (KIND=nag wp) array

Output

On exit: the canonical variate loadings for the x variables. CVX(i, j) contains the loading coefficient for the ith x variable on the jth canonical variate.

14: LDCVX – INTEGER

Input

On entry: the first dimension of the array CVX as declared in the (sub)program from which G03ADF is called.

Constraint: LDCVX \geq NX.

15: MCV – INTEGER

Input

On entry: an upper limit to the number of canonical variates.

Constraint: $MCV \ge min(NX, NY)$.

16: CVY(LDCVY,MCV) – REAL (KIND=nag wp) array

Output

On exit: the canonical variate loadings for the y variables. CVY(i, j) contains the loading coefficient for the ith y variable on the jth canonical variate.

17: LDCVY – INTEGER

Input

On entry: the first dimension of the array CVY as declared in the (sub)program from which G03ADF is called.

Constraint: LDCVY > NY.

18: TOL – REAL (KIND=nag_wp)

Input

On entry: the value of TOL is used to decide if the variables are of full rank and, if not, what is the rank of the variables. The smaller the value of TOL the stricter the criterion for selecting the singular value decomposition. If a non-negative value of TOL less than *machine precision* is entered, the square root of *machine precision* is used instead.

Constraint: $TOL \ge 0.0$.

19: WK(IWK) - REAL (KIND=nag wp) array

Workspace

20: IWK - INTEGER

Input

On entry: the dimension of the array WK as declared in the (sub)program from which G03ADF is called.

G03ADF.4 Mark 24

Constraints:

```
if NX \ge NY, IWK \ge N \times NX + NX + NY + max((5 \times (NX - 1) + NX \times NX), N \times NY) + 1; if NX < NY, IWK \ge N \times NY + NX + NY + max((5 \times (NY - 1) + NY \times NY), N \times NX) + 1.
```

21: IFAIL – INTEGER

Input/Output

On entry: IFAIL must be set to 0, -1 or 1. If you are unfamiliar with this parameter you should refer to Section 3.3 in the Essential Introduction for details.

For environments where it might be inappropriate to halt program execution when an error is detected, the value -1 or 1 is recommended. If the output of error messages is undesirable, then the value 1 is recommended. Otherwise, if you are not familiar with this parameter, the recommended value is 0. When the value -1 or 1 is used it is essential to test the value of IFAIL on exit.

On exit: IFAIL = 0 unless the routine detects an error or a warning has been flagged (see Section 6).

6 Error Indicators and Warnings

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

Errors or warnings detected by the routine:

```
IFAIL = 1
```

```
On entry, NX < 1,
          NY < 1,
or
          M < NX + NY,
or
or
          N \leq NX + NY,
          MCV < min(NX, NY),
or
          LDZ < N,
or
          LDCVX < NX,
or
          LDCVY < NY,
or
          LDE < min(NX, NY),
or
          NX \ge NY and
or
          IWK < N \times NX + NX + NY + max((5 \times (NX - 1) + NX \times NX), N \times NY),
          NX < NY and
or
          IWK < N \times NY + NX + NY + max((5 \times (NY - 1) + NY \times NY), N \times NX),
          WEIGHT \neq 'U' or 'W'.
or
          TOL < 0.0.
or
```

IFAIL = 2

On entry, a WEIGHT = 'W' and value of WT < 0.0.

IFAIL = 3

On entry, the number of x variables to be included in the analysis as indicated by ISZ is not equal to NX.

or the number of y variables to be included in the analysis as indicated by ISZ is not equal to NY.

IFAIL = 4

On entry, the effective number of observations is less than NX + NY + 1.

G03ADF NAG Library Manual

IFAIL = 5

A singular value decomposition has failed to converge. See F02WUF. This is an unlikely error exit

IFAIL = 6

A canonical correlation is equal to 1. This will happen if the x and y variables are perfectly correlated.

```
IFAIL = 7
```

On entry, the rank of the X matrix or the rank of the Y matrix is 0. This will happen if all the x or y variables are constants.

7 Accuracy

As the computation involves the use of orthogonal matrices and a singular value decomposition rather than the traditional computing of a sum of squares matrix and the use of an eigenvalue decomposition, G03ADF should be less affected by ill-conditioned problems.

8 Further Comments

None.

9 Example

This example has nine observations and two variables in each set of the four variables read in, the second and third are x variables while the first and last are y variables. Canonical variate analysis is performed and the results printed.
