NAG Library Routine Document

F07GHF (DPPRFS)

Note: before using this routine, please read the Users' Note for your implementation to check the interpretation of **_bold italicised_** terms and other implementation-dependent details.

1   Purpose

F07GHF (DPPRFS) returns error bounds for the solution of a real symmetric positive definite system of linear equations with multiple right-hand sides, $AX = B$, using packed storage. It improves the solution by iterative refinement, in order to reduce the backward error as much as possible.

2   Specification

```
SUBROUTINE F07GHF (UPLO, N, NRHS, AP, AFP, B, LDB, X, LDX, FERR, BERR,    &
                   WORK, IWORK, INFO)

INTEGER           N, NRHS, LDB, LDX, IWORK(N), INFO
REAL (KIND=nag_wp) AP(*), AFP(*), B(LDB,*), X(LDX,*), FERR(NRHS),         &
                   BERR(NRHS), WORK(3*N)
CHARACTER(1)      UPLO
```

The routine may be called by its LAPACK name **_dpprfs_**.

3   Description

F07GHF (DPPRFS) returns the backward errors and estimated bounds on the forward errors for the solution of a real symmetric positive definite system of linear equations with multiple right-hand sides $AX = B$, using packed storage. The routine handles each right-hand side vector (stored as a column of the matrix B) independently, so we describe the function of F07GHF (DPPRFS) in terms of a single right-hand side b and solution x.

Given a computed solution x, the routine computes the *component-wise backward error* β. This is the size of the smallest relative perturbation in each element of A and b such that x is the exact solution of a perturbed system

$$(A + \delta A)x = b + \delta b$$
$$\left|\delta a_{ij}\right| \le \beta\left|a_{ij}\right| \quad \text{and} \quad |\delta b_i| \le \beta|b_i|.$$

Then the routine estimates a bound for the *component-wise forward error* in the computed solution, defined by:

$$\max_i|x_i - \hat{x}_i|/\max_i|x_i|$$

where $\hat{x}$ is the true solution.

For details of the method, see the F07 Chapter Introduction.

4   References

5 Arguments

1: UPLO – CHARACTER(1) *Input*

On entry: specifies whether the upper or lower triangular part of A is stored and how A is to be factorized.

UPLO = 'U'
   The upper triangular part of A is stored and A is factorized as $U^{\mathrm{T}}U$, where U is upper triangular.

UPLO = 'L'
   The lower triangular part of A is stored and A is factorized as LL^{T}, where L is lower triangular.

Constraint: UPLO = 'U' or 'L'.

2: N – INTEGER *Input*

On entry: n, the order of the matrix A.

Constraint: $N \geq 0$.

3: NRHS – INTEGER *Input*

On entry: r, the number of right-hand sides.

Constraint: $NRHS \geq 0$.

4: AP($*$) – REAL (KIND=nag_wp) array *Input*

Note: the dimension of the array AP must be at least $\max(1, N \times (N+1)/2)$.

On entry: the n by n original symmetric positive definite matrix A as supplied to F07GDF (DPPTRF).

5: AFP($*$) – REAL (KIND=nag_wp) array *Input*

Note: the dimension of the array AFP must be at least $\max(1, N \times (N+1)/2)$.

On entry: the Cholesky factor of A stored in packed form, as returned by F07GDF (DPPTRF).

6: B(LDB, $*$) – REAL (KIND=nag_wp) array *Input*

Note: the second dimension of the array B must be at least $\max(1, NRHS)$.

On entry: the n by r right-hand side matrix B.

7: LDB – INTEGER *Input*

On entry: the first dimension of the array B as declared in the (sub)program from which F07GHF (DPPRFS) is called.

Constraint: $LDB \geq \max(1, N)$.

8: X(LDX, $*$) – REAL (KIND=nag_wp) array *Input/Output*

Note: the second dimension of the array X must be at least $\max(1, NRHS)$.

On entry: the n by r solution matrix X, as returned by F07GEF (DPPTRS).

On exit: the improved solution matrix X.

9:    LDX – INTEGER   *Input*

   On entry: the first dimension of the array X as declared in the (sub)program from which F07GHF (DPPRFS) is called.

   Constraint: $LDX \geq \max(1, N)$.

10:   FERR(NRHS) – REAL (KIND=nag_wp) array   *Output*

   On exit: $FERR(j)$ contains an estimated error bound for the jth solution vector, that is, the jth column of X, for $j = 1, 2, \ldots, r$.

11:   BERR(NRHS) – REAL (KIND=nag_wp) array   *Output*

   On exit: $BERR(j)$ contains the component-wise backward error bound β for the jth solution vector, that is, the jth column of X, for $j = 1, 2, \ldots, r$.

12:   WORK($3 \times N$) – REAL (KIND=nag_wp) array   *Workspace*

13:   IWORK(N) – INTEGER array   *Workspace*

14:   INFO – INTEGER   *Output*

   On exit: $INFO = 0$ unless the routine detects an error (see Section 6).

6   Error Indicators and Warnings

INFO < 0

   If $INFO = -i$, argument i had an illegal value. An explanatory message is output, and execution of the program is terminated.

7   Accuracy

The bounds returned in FERR are not rigorous, because they are estimated, not computed exactly; but in practice they almost always overestimate the actual error.

8   Parallelism and Performance

F07GHF (DPPRFS) is threaded by NAG for parallel execution in multithreaded implementations of the NAG Library.

F07GHF (DPPRFS) makes calls to BLAS and/or LAPACK routines, which may be threaded within the vendor library used by this implementation. Consult the documentation for the vendor library for further information.

Please consult the X06 Chapter Introduction for information on how to control and interrogate the OpenMP environment used within this routine. Please also consult the Users' Note for your implementation for any additional implementation-specific information.

9   Further Comments

For each right-hand side, computation of the backward error involves a minimum of $4n^2$ floating-point operations. Each step of iterative refinement involves an additional $6n^2$ operations. At most five steps of iterative refinement are performed, but usually only 1 or 2 steps are required.

Estimating the forward error involves solving a number of systems of linear equations of the form $Ax = b$; the number is usually 4 or 5 and never more than 11. Each solution involves approximately $2n^2$ operations.

The complex analogue of this routine is F07GVF (ZPPRFS).

10 Example

This example solves the system of equations $AX = B$ using iterative refinement and to compute the forward and backward error bounds, where

$$A = \begin{pmatrix} 4.16 & -3.12 & 0.56 & -0.10 \\ -3.12 & 5.03 & -0.83 & 1.18 \\ 0.56 & -0.83 & 0.76 & 0.34 \\ -0.10 & 1.18 & 0.34 & 1.18 \end{pmatrix} \quad \text{and} \quad B = \begin{pmatrix} 8.70 & 8.30 \\ -13.35 & 2.13 \\ 1.89 & 1.61 \\ -4.14 & 5.00 \end{pmatrix}.$$

Here A is symmetric positive definite, stored in packed form, and must first be factorized by F07GDF (DPPTRF).
