3 Description

nag_dgghrd (f08wec) is the third step in the solution of the real generalized eigenvalue problem

$$Ax = \lambda Bx.$$

The (optional) first step balances the two matrices using nag_dggbal (f08whc). In the second step, matrix B is reduced to upper triangular form using the QR factorization function nag_dgeqr (f08aec) and this orthogonal transformation Q is applied to matrix A by calling nag_dormqr (f08agc).

nag_dgghrd (f08wec) reduces a pair of real matrices (A, B), where B is upper triangular, to the generalized upper Hessenberg form using orthogonal transformations. This two-sided transformation is of the form

$$\begin{aligned} Q^T A Z &= H \\ Q^T B Z &= T \end{aligned}$$

where H is an upper Hessenberg matrix, T is an upper triangular matrix and Q and Z are orthogonal matrices determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices Q_1 and Z_1 , so that

$$\begin{aligned} Q_1 A Z_1^T &= (Q_1 Q) H (Z_1 Z)^T, \\ Q_1 B Z_1^T &= (Q_1 Q) T (Z_1 Z)^T. \end{aligned}$$

7 Accuracy

The reduction to the generalized Hessenberg form is implemented using orthogonal transformations which are backward stable.

8 Parallelism and Performance

`nag_dgghrd` (f08wec) is not threaded by NAG in any implementation.

`nag_dgghrd` (f08wec) makes calls to BLAS and/or LAPACK routines, which may be threaded within the vendor library used by this implementation. Consult the documentation for the vendor library for further information.

Please consult the Users' Note for your implementation for any additional implementation-specific information.

9 Further Comments

This function is usually followed by `nag_dhgeqz` (f08xec) which implements the QZ algorithm for computing generalized eigenvalues of a reduced pair of matrices.

The complex analogue of this function is `nag_zgghrd` (f08wsc).

10 Example

See Section 10 in `nag_dhgeqz` (f08xec) and `nag_dtgevc` (f08ykc).
