nag_quad_1d_fin_smooth (d01bdc)

1 Purpose

nag_quad_1d_fin_smooth (d01bdc) calculates an approximation to the integral of a function over a finite interval $[a, b]$:

$$I = \int_a^b f(x) dx.$$

It is non-adaptive and as such is recommended for the integration of ‘smooth’ functions. These **exclude** integrands with singularities, derivative singularities or high peaks on $[a, b]$, or which oscillate too strongly on $[a, b]$.

2 Specification

```
#include <nag.h>
#include <nagd01.h>
void nag_quad_1d_fin_smooth (
    double (*f)(double x, Nag_Comm *comm),
    double a, double b, double epsabs, double epsrel, double *result,
    double *abserr, Nag_Comm *comm)
```

3 Description

nag_quad_1d_fin_smooth (d01bdc) is based on the QUADPACK routine QNG (see Piessens *et al.* (1983)). It is a non-adaptive function which uses as its basic rules, the Gauss 10-point and 21-point formulae. If the accuracy criterion is not met, formulae using 43 and 87 points are used successively, stopping whenever the accuracy criterion is satisfied.

This function is designed for smooth integrands only.

5 Arguments

- | | | |
|----|---|--------------------------|
| 1: | f – function, supplied by the user | <i>External Function</i> |
| | f must return the value of the integrand f at a given point. | |

The specification of **f** is:

```
double f (double x, Nag_Comm *comm)
```

- | | | |
|----|-------------------|--------------|
| 1: | x – double | <i>Input</i> |
|----|-------------------|--------------|

On entry: the point at which the integrand f must be evaluated.

2: **comm** – Nag_Comm *

Pointer to structure of type Nag_Comm; the following members are relevant to **f**.

user – double *

iuser – Integer *

p – Pointer

The type Pointer will be `void *`. Before calling `nag_quad_1d_fin_smooth` (d01bdc) you may allocate memory and initialize these pointers with various quantities for use by **f** when called from `nag_quad_1d_fin_smooth` (d01bdc) (see Section 3.2.1.1 in the Essential Introduction).

2: **a** – double

Input

On entry: a , the lower limit of integration.

3: **b** – double

Input

On entry: b , the upper limit of integration. It is not necessary that $a < b$.

4: **epsabs** – double

Input

On entry: the absolute accuracy required. If **epsabs** is negative, the absolute value is used. See Section 7.

5: **epsrel** – double

Input

On entry: the relative accuracy required. If **epsrel** is negative, the absolute value is used. See Section 7.

6: **result** – double *

Output

On exit: the approximation to the integral I .

7: **abserr** – double *

Output

On exit: an estimate of the modulus of the absolute error, which should be an upper bound for $|I - \text{result}|$.

8: **comm** – Nag_Comm *

The NAG communication argument (see Section 3.2.1.1 in the Essential Introduction).

6 Error Indicators and Warnings

There are no specific errors detected by `nag_quad_1d_fin_smooth` (d01bdc). However, if **abserr** is greater than

$$\max\{\text{epsabs}, \text{epsrel} \times |\text{result}|\}$$

this indicates that the function has probably failed to achieve the requested accuracy within 87 function evaluations.

7 Accuracy

`nag_quad_1d_fin_smooth` (d01bdc) attempts to compute an approximation, **result**, such that:

$$|I - \text{result}| \leq tol,$$

where

$$tol = \max\{|\text{epsabs}|, |\text{epsrel}| \times |I|\},$$

and **epsabs** and **epsrel** are user-specified absolute and relative error tolerances. There can be no guarantee that this is achieved, and you are advised to subdivide the interval if you have any doubts about the accuracy obtained. Note that **abserr** contains an estimated bound on $|I - \text{result}|$.

8 Parallelism and Performance

Not applicable.

9 Further Comments

The time taken by `nag_quad_1d_fin_smooth` (`d01bdc`) depends on the integrand and the accuracy required.

10 Example

This example computes

$$\int_0^1 x^2 \sin(10\pi x) dx.$$
