

## NAG Library Function Document

### nag\_opt\_check\_deriv (e04hcc)

#### 1 Purpose

nag\_opt\_check\_deriv (e04hcc) checks that a user-defined C function for evaluating an objective function and its first derivatives produces derivative values which are consistent with the function values calculated.

#### 2 Specification

```
#include <nag.h>
#include <nage04.h>

void nag_opt_check_deriv (Integer n,
    void (*objfun)(Integer n, const double x[], double *objf, double g[],
        Nag_Comm *comm),
    const double x[], double *objf, double g[], Nag_Comm *comm,
    NagError *fail)
```

#### 3 Description

The function nag\_opt\_bounds\_deriv (e04kbc) for minimizing a function of several variables requires you to supply a C function to evaluate the objective function  $F(x_1, x_2, \dots, x_n)$  and its first derivatives. nag\_opt\_check\_deriv (e04hcc) is designed to check the derivatives calculated by such a user-supplied function. As well as the function to be checked (**objfun**), you must supply a point  $x = (x_1, x_2, \dots, x_n)^T$  at which the check is to be made.

nag\_opt\_check\_deriv (e04hcc) first calls the supplied function **objfun** to evaluate  $F$  and its first derivatives  $g_j = \frac{\partial F}{\partial x_j}$ , for  $j = 1, 2, \dots, n$  at  $x$ . The components of the user-supplied derivatives along two orthogonal directions (defined by unit vectors  $p_1$  and  $p_2$ , say) are then calculated; these will be  $g^T p_1$  and  $g^T p_2$  respectively. The same components are also estimated by finite differences, giving quantities

$$v_k = \frac{F(x + hp_k) - F(x)}{h}, \quad k = 1, 2$$

where  $h$  is a small positive scalar. If the relative difference between  $v_1$  and  $g^T p_1$  or between  $v_2$  and  $g^T p_2$  is judged too large, an error indicator is set.

#### 4 References

None.

#### 5 Arguments

- 1: **n** – Integer *Input*  
*On entry:* the number  $n$  of independent variables in the objective function.  
*Constraint:*  $n \geq 1$ .
- 2: **objfun** – function, supplied by the user *External Function*  
**objfun** must evaluate the objective function and its first derivatives at a given point. (The minimization function nag\_opt\_bounds\_deriv (e04kbc) gives you the option of resetting an argument, **comm**→**flag**, to terminate the minimization process immediately. nag\_opt\_check\_deriv

(e04hcc) will also terminate immediately, without finishing the checking process, if the argument in question is reset to a negative value.)

The specification of <b>objfun</b> is:	
void objfun (Integer n, const double x[], double *objf, double g[], Nag_Comm *comm)	
1:	<b>n</b> – Integer <span style="float:right"><i>Input</i></span> <i>On entry:</i> the number $n$ of variables.
2:	<b>x[n]</b> – const double <span style="float:right"><i>Input</i></span> <i>On entry:</i> the point $x$ at which $F$ and its derivatives are required.
3:	<b>objf</b> – double * <span style="float:right"><i>Output</i></span> <i>On exit:</i> <b>objfun</b> must set <b>objf</b> to the value of the objective function $F$ at the current point $x$ . If it is not possible to evaluate $F$ then <b>objfun</b> should assign a negative value to <b>comm</b> → <b>flag</b> ; nag_opt_check_deriv (e04hcc) will then terminate.
4:	<b>g[n]</b> – double <span style="float:right"><i>Output</i></span> <i>On exit:</i> unless <b>comm</b> → <b>flag</b> is reset to a negative number, <b>objfun</b> must set <b>g[j – 1]</b> to the value of the first derivative $\frac{\partial F}{\partial x_j}$ at the current point $x$ for $j = 1, 2, \dots, n$
5:	<b>comm</b> – Nag_Comm * Pointer to structure of type Nag_Comm; the following members are relevant to <b>objfun</b> .
	<b>flag</b> – Integer <span style="float:right"><i>Input/Output</i></span> <i>On entry:</i> <b>comm</b> → <b>flag</b> will be set to 2. <i>On exit:</i> if <b>objfun</b> resets <b>comm</b> → <b>flag</b> to some negative number then nag_opt_check_deriv (e04hcc) will terminate immediately with the error indicator NE_USER_STOP. If <b>fail</b> is supplied to nag_opt_check_deriv (e04hcc), <b>fail.errnum</b> will be set to your setting of <b>comm</b> → <b>flag</b> .
	<b>first</b> – Nag_Boolean <span style="float:right"><i>Input</i></span> <i>On entry:</i> will be set to Nag_TRUE on the first call to <b>objfun</b> and Nag_FALSE for all subsequent calls.
	<b>nf</b> – Integer <span style="float:right"><i>Input</i></span> <i>On entry:</i> the number of calculations of the objective function; this value will be equal to the number of calls made to <b>objfun</b> including the current one.
	<b>user</b> – double * <b>iuser</b> – Integer * <b>p</b> – Pointer The type Pointer will be void * with a C compiler that defines void * and char * otherwise. Before calling nag_opt_check_deriv (e04hcc) these pointers may be allocated memory and initialized with various quantities for use by <b>objfun</b> when called from nag_opt_check_deriv (e04hcc).

The array **x** must **not** be changed by **objfun**.

- 3: **x[n]** – const double *Input*  
*On entry:*  $x[j - 1]$ , for  $j = 1, 2, \dots, n$ , must be set to the coordinates of a suitable point at which to check the derivatives calculated by **objfun**. ‘Obvious’ settings, such as 0.0 or 1.0, should not be used since, at such particular points, incorrect terms may take correct values (particularly zero), so that errors could go undetected. Similarly, it is preferable that no two elements of **x** should be the same.
- 4: **objf** – double \* *Output*  
*On exit:* unless you set **comm**→**flag** negative in the first call of **objfun**, **objf** contains the value of the objective function  $F(x)$  at the point given in **x**.
- 5: **g[n]** – double *Output*  
*On exit:* unless you set **comm**→**flag** negative in the first call of **objfun**,  $g[j - 1]$  contains the value of the derivative  $\frac{\partial F}{\partial x_j}$  at the point given in **x**, as calculated by **objfun**, for  $j = 1, 2, \dots, n$ .
- 6: **comm** – Nag\_Comm \* *Input/Output*  
**Note:** **comm** is a NAG defined type (see Section 3.2.1.1 in the Essential Introduction).  
*On entry/exit:* structure containing pointers for communication with the user-defined function; see the above description of **objfun** for details. If you do not need to make use of this communication feature the null pointer NAGCOMM\_NULL may be used in the call to nag\_opt\_check\_deriv (e04hcc); **comm** will then be declared internally for use in calls to **objfun**.
- 7: **fail** – NagError \* *Input/Output*  
The NAG error argument (see Section 3.6 in the Essential Introduction).

## 6 Error Indicators and Warnings

### NE\_ALLOC\_FAIL

Dynamic memory allocation failed.

### NE\_DERIV\_ERRORS

Large errors were found in the derivatives of the objective function.

You should check carefully the derivation and programming of expressions for the derivatives of  $F(x)$ , because it is very unlikely that **objfun** is calculating them correctly.

### NE\_INT\_ARG\_LT

On entry, **n** =  $\langle value \rangle$ .  
Constraint:  $n \geq 1$ .

### NE\_USER\_STOP

User requested termination, user flag value =  $\langle value \rangle$ .

This exit occurs if you set **comm**→**flag** to a negative value in **objfun**. If **fail** is supplied the value of **fail.errnum** will be the same as your setting of **comm**→**flag**. The check on **objfun** will not have been completed.

## 7 Accuracy

**fail** is set to NE\_DERIV\_ERRORS if

$$(v_k - g^T p_k)^2 \geq h \times ((g^T p_k)^2 + 1)$$

for  $k = 1$  or  $2$ . (See Section 3 for definitions of the quantities involved.) The scalar  $h$  is set equal to  $\sqrt{\epsilon}$ , where  $\epsilon$  is the *machine precision* as given by nag\_machine\_precision (X02AJC).

## 8 Parallelism and Performance

Not applicable.

## 9 Further Comments

The user-defined function **objfun** is called three times.

Before using nag\_opt\_check\_deriv (e04hcc) to check the calculation of first derivatives, you should be confident that **objfun** is calculating  $F$  correctly. The usual way of checking the calculation of the function is to compare values of  $F(x)$  calculated by **objfun** at non-trivial points  $x$  with values calculated independently. ('Non-trivial' means that, as when setting  $x$  before calling nag\_opt\_check\_deriv (e04hcc), coordinates such as 0.0 or 1.0 should be avoided.)

## 10 Example

Suppose that it is intended to use nag\_opt\_bounds\_deriv (e04kbc) to minimize

$$F = (x_1 + 10x_2)^2 + 5(x_3 - x_4)^2 + (x_2 - 2x_3)^4 + 10(x_1 - x_4)^4.$$

The following program could be used to check the first derivatives calculated by the required function **objfun**. (The test of whether **comm**→**flag**  $\neq 0$  in **objfun** is present for when **objfun** is called by nag\_opt\_bounds\_deriv (e04kbc). nag\_opt\_check\_deriv (e04hcc) will always call **objfun** with **comm**→**flag** set to 2.)

## 10.2 Program Data

None.

## 10.3 Program Results

nag\_opt\_check\_deriv (e04hcc) Example Program Results

The test point is:

1.4600 -0.8200 0.5700 1.2100

First derivatives are consistent with function values.

At the test point, objfun gives the function value 6.2273e+01  
and the 1st derivatives

-1.285e+01 -1.649e+02 5.384e+01 5.775e+00
