NAG Library Function Document

nag_dgeqrt (f08abc)

1 Purpose

nag_dgeqrt (f08abc) recursively computes, with explicit blocking, the QR factorization of a real m by n matrix.

2 Specification

3 Description

nag_dgeqrt (f08abc) forms the QR factorization of an arbitrary rectangular real m by n matrix. No pivoting is performed.

It differs from nag_dgeqrf (f08aec) in that it: requires an explicit block size; stores reflector factors that are upper triangular matrices of the chosen block size (rather than scalars); and recursively computes the QR factorization based on the algorithm of Elmroth and Gustavson (2000).

If $m \ge n$, the factorization is given by:

$$A = Q\binom{R}{0},$$

where R is an n by n upper triangular matrix and Q is an m by m orthogonal matrix. It is sometimes more convenient to write the factorization as

$$A = \begin{pmatrix} Q_1 & Q_2 \end{pmatrix} \begin{pmatrix} R \\ 0 \end{pmatrix},$$

which reduces to

$$A = Q_1 R$$
,

where Q_1 consists of the first n columns of Q, and Q_2 the remaining m-n columns.

If m < n, R is upper trapezoidal, and the factorization can be written

$$A = Q(R_1 \quad R_2),$$

where R_1 is upper triangular and R_2 is rectangular.

The matrix Q is not formed explicitly but is represented as a product of $\min(m, n)$ elementary reflectors (see the f08 Chapter Introduction for details). Functions are provided to work with Q in this representation (see Section 9).

Note also that for any k < n, the information returned represents a QR factorization of the first k columns of the original matrix A.

5 Arguments

1: **order** – Nag OrderType

Input

On entry: the **order** argument specifies the two-dimensional storage scheme being used, i.e., row-major ordering or column-major ordering. C language defined storage is specified by **order** = Nag_RowMajor. See Section 3.2.1.3 in the Essential Introduction for a more detailed explanation of the use of this argument.

Constraint: order = Nag_RowMajor or Nag_ColMajor.

2: \mathbf{m} – Integer

On entry: m, the number of rows of the matrix A.

Constraint: $\mathbf{m} \geq 0$.

3: \mathbf{n} – Integer

On entry: n, the number of columns of the matrix A.

Constraint: $\mathbf{n} \geq 0$.

4: **nb** – Integer Input

On entry: the explicitly chosen block size to be used in computing the QR factorization. See Section 9 for details.

Constraints:

```
nb \ge 1; if min(m, n) > 0, nb \le min(m, n).
```

5: $\mathbf{a}[dim]$ – double

Input/Output

Note: the dimension, dim, of the array a must be at least

```
\max(1, \mathbf{pda} \times \mathbf{n}) when \mathbf{order} = \text{Nag\_ColMajor}; \max(1, \mathbf{m} \times \mathbf{pda}) when \mathbf{order} = \text{Nag\_RowMajor}.
```

The (i, j)th element of the matrix A is stored in

```
\mathbf{a}[(j-1) \times \mathbf{pda} + i - 1] when \mathbf{order} = \text{Nag\_ColMajor};
\mathbf{a}[(i-1) \times \mathbf{pda} + j - 1] when \mathbf{order} = \text{Nag\_RowMajor}.
```

On entry: the m by n matrix A.

On exit: if $m \ge n$, the elements below the diagonal are overwritten by details of the orthogonal matrix Q and the upper triangle is overwritten by the corresponding elements of the n by n upper triangular matrix R.

If m < n, the strictly lower triangular part is overwritten by details of the orthogonal matrix Q and the remaining elements are overwritten by the corresponding elements of the m by n upper trapezoidal matrix R.

6: **pda** – Integer Input

On entry: the stride separating row or column elements (depending on the value of **order**) in the array **a**.

f08abc.2 Mark 25

Constraints:

```
if order = Nag_ColMajor, pda \geq \max(1, \mathbf{m}); if order = Nag_RowMajor, pda \geq \max(1, \mathbf{n}).
```

7: $\mathbf{t}[dim]$ – double

Output

Note: the dimension, dim, of the array t must be at least

```
\max(1, \mathbf{pdt} \times \min(\mathbf{m}, \mathbf{n})) when \mathbf{order} = \text{Nag-ColMajor}; \max(1, \mathbf{nb} \times \mathbf{pdt}) when \mathbf{order} = \text{Nag-RowMajor}.
```

The (i, j)th element of the matrix T is stored in

```
\mathbf{t}[(j-1) \times \mathbf{pdt} + i - 1] when \mathbf{order} = \text{Nag\_ColMajor};
\mathbf{t}[(i-1) \times \mathbf{pdt} + j - 1] when \mathbf{order} = \text{Nag\_RowMajor}.
```

On exit: further details of the orthogonal matrix Q. The number of blocks is $b = \left\lceil \frac{k}{\mathbf{n}\mathbf{b}} \right\rceil$, where $k = \min(m, n)$ and each block is of order $\mathbf{n}\mathbf{b}$ except for the last block, which is of order $k - (b - 1) \times \mathbf{n}\mathbf{b}$. For each of the blocks, an upper triangular block reflector factor is computed: T_1, T_2, \ldots, T_b . These are stored in the $\mathbf{n}\mathbf{b}$ by n matrix T as $T = [T_1 | T_2 | \ldots | T_b]$.

8: **pdt** – Integer

Input

On entry: the stride separating row or column elements (depending on the value of **order**) in the array **t**.

Constraints:

```
if order = Nag_ColMajor, pdt \geq nb;
if order = Nag_RowMajor, pdt \geq max(1, min(m, n)).
```

9: **fail** – NagError *

Input/Output

The NAG error argument (see Section 3.6 in the Essential Introduction).

6 Error Indicators and Warnings

NE_ALLOC_FAIL

Dynamic memory allocation failed.

See Section 3.2.1.2 in the Essential Introduction for further information.

NE BAD PARAM

On entry, argument (value) had an illegal value.

NE INT

```
On entry, \mathbf{m} = \langle value \rangle.
Constraint: \mathbf{m} \geq 0.
On entry, \mathbf{n} = \langle value \rangle.
Constraint: \mathbf{n} \geq 0.
```

NE INT 2

```
On entry, \mathbf{pda} = \langle value \rangle and \mathbf{m} = \langle value \rangle.
Constraint: \mathbf{pda} \geq \max(1, \mathbf{m}).
On entry, \mathbf{pda} = \langle value \rangle and \mathbf{n} = \langle value \rangle.
Constraint: \mathbf{pda} \geq \max(1, \mathbf{n}).
On entry, \mathbf{pdt} = \langle value \rangle and \mathbf{nb} = \langle value \rangle.
Constraint: \mathbf{pdt} \geq \mathbf{nb}.
```

Mark 25 f08abc.3

NAG Library Manual

NE INT 3

```
On entry, \mathbf{nb} = \langle value \rangle, \mathbf{m} = \langle value \rangle and \mathbf{n} = \langle value \rangle.
Constraint: \mathbf{nb} \geq 1 and if \min(\mathbf{m}, \mathbf{n}) > 0, \mathbf{nb} \leq \min(\mathbf{m}, \mathbf{n}).
On entry, \mathbf{pdt} = \langle value \rangle, \mathbf{m} = \langle value \rangle and \mathbf{n} = \langle value \rangle.
Constraint: \mathbf{pdt} \geq \max(1, \min(\mathbf{m}, \mathbf{n})).
```

NE INTERNAL ERROR

An internal error has occurred in this function. Check the function call and any array sizes. If the call is correct then please contact NAG for assistance.

An unexpected error has been triggered by this function. Please contact NAG. See Section 3.6.6 in the Essential Introduction for further information.

NE_NO_LICENCE

Your licence key may have expired or may not have been installed correctly. See Section 3.6.5 in the Essential Introduction for further information.

7 Accuracy

The computed factorization is the exact factorization of a nearby matrix (A + E), where

$$||E||_2 = O(\epsilon)||A||_2,$$

and ϵ is the *machine precision*.

8 Parallelism and Performance

nag dgeqrt (f08abc) is not threaded by NAG in any implementation.

nag_dgeqrt (f08abc) makes calls to BLAS and/or LAPACK routines, which may be threaded within the vendor library used by this implementation. Consult the documentation for the vendor library for further information.

Please consult the X06 Chapter Introduction for information on how to control and interrogate the OpenMP environment used within this function. Please also consult the Users' Note for your implementation for any additional implementation-specific information.

9 Further Comments

The total number of floating-point operations is approximately $\frac{2}{3}n^2(3m-n)$ if $m \ge n$ or $\frac{2}{3}m^2(3n-m)$ if m < n.

To apply Q to an arbitrary real rectangular matrix C, nag_dgeqrt (f08abc) may be followed by a call to nag_dgemqrt (f08acc). For example,

```
nag_dgemqrt(order,Nag_LeftSide,Nag_Trans,m,p,MIN(m,n),nb,a,pda,t,pdt,
c,pdc,&fail)
```

forms $C = Q^{T}C$, where C is m by p.

To form the orthogonal matrix Q explicitly, simply initialize the m by m matrix C to the identity matrix and form C = QC using nag dgemqrt (f08acc) as above.

The block size, \mathbf{nb} , used by $\mathrm{nag_dgeqrt}$ (f08abc) is supplied explicitly through the interface. For moderate and large sizes of matrix, the block size can have a marked effect on the efficiency of the algorithm with the optimal value being dependent on problem size and platform. A value of $\mathbf{nb} = 64 \ll \min(m,n)$ is likely to achieve good efficiency and it is unlikely that an optimal value would exceed 340.

To compute a QR factorization with column pivoting, use nag_dtpqrt (f08bbc) or nag_dgeqpf (f08bec).

f08abc.4 Mark 25

The complex analogue of this function is nag zgeqrt (f08apc).

10 Example

This example solves the linear least squares problems

minimize
$$||Ax_i - b_i||_2$$
, $i = 1, 2$

where b_1 and b_2 are the columns of the matrix B,

$$A = \begin{pmatrix} -0.57 & -1.28 & -0.39 & 0.25 \\ -1.93 & 1.08 & -0.31 & -2.14 \\ 2.30 & 0.24 & 0.40 & -0.35 \\ -1.93 & 0.64 & -0.66 & 0.08 \\ 0.15 & 0.30 & 0.15 & -2.13 \\ -0.02 & 1.03 & -1.43 & 0.50 \end{pmatrix} \quad \text{and} \quad B = \begin{pmatrix} -2.67 & 0.41 \\ -0.55 & -3.10 \\ 3.34 & -4.01 \\ -0.77 & 2.76 \\ 0.48 & -6.17 \\ 4.10 & 0.21 \end{pmatrix}.$$
