### 3 Description

nag\_binary\_aon\_greeks (s30cdc) computes the price of a binary or digital asset-or-nothing option, together with the Greeks or sensitivities, which are the partial derivatives of the option price with respect to certain of the other input parameters. This option pays the underlying asset itself,  $S$ , at expiration if the option is in-the-money (see Section 2.4 in the s Chapter Introduction). For a strike price,  $X$ , underlying asset price,  $S$ , and time to expiry,  $T$ , the payoff is therefore  $S$ , if  $S > X$  for a call or  $S < X$  for a put. Nothing is paid out when this condition is not met.

The price of a call with volatility,  $\sigma$ , risk-free interest rate,  $r$ , and annualised dividend yield,  $q$ , is

$$P_{\text{call}} = S e^{-qT} \Phi(d_1)$$

and for a put,

$$P_{\text{put}} = S e^{-qT} \Phi(-d_1)$$

where  $\Phi$  is the cumulative Normal distribution function,

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x \exp(-y^2/2) dy,$$

and

$$d_1 = \frac{\ln(S/X) + (r - q + \sigma^2/2)T}{\sigma\sqrt{T}}.$$

The option price  $P_{ij} = P(X = X_i, T = T_j)$  is computed for each strike price in a set  $X_i$ ,  $i = 1, 2, \dots, m$ , and for each expiry time in a set  $T_j$ ,  $j = 1, 2, \dots, n$ .

## 7 Accuracy

The accuracy of the output is dependent on the accuracy of the cumulative Normal distribution function,  $\Phi$ . This is evaluated using a rational Chebyshev expansion, chosen so that the maximum relative error in the expansion is of the order of the **machine precision** (see nag\_cumul\_normal (s15abc) and nag\_erfc (s15adc)). An accuracy close to **machine precision** can generally be expected.

## 8 Parallelism and Performance

nag\_binary\_aon\_greeks (s30cdc) is threaded by NAG for parallel execution in multithreaded implementations of the NAG Library.

Please consult the X06 Chapter Introduction for information on how to control and interrogate the OpenMP environment used within this function. Please also consult the Users' Note for your implementation for any additional implementation-specific information.

## 9 Further Comments

None.

## 10 Example

This example computes the price of an asset-or-nothing put with a time to expiry of 292 days, a stock price of 70 and a strike price of 65. The risk-free interest rate is 5% per year, there is an annual dividend return of 3% and the volatility is 15% per year.
