NAG Library Routine Document

F08KNF (ZGELSS)

Note: before using this routine, please read the Users' Note for your implementation to check the interpretation of **bold italicised** terms and other implementation-dependent details.

1   Purpose

F08KNF (ZGELSS) computes the minimum norm solution to a complex linear least squares problem

$$\min_x \|b - Ax\|_2.$$

2   Specification

```
SUBROUTINE F08KNF (M, N, NRHS, A, LDA, B, LDB, S, RCOND, RANK, WORK,      &
                   LWORK, RWORK, INFO)

INTEGER            M, N, NRHS, LDA, LDB, RANK, LWORK, INFO
REAL (KIND=nag_wp)   S(*), RCOND, RWORK(*)
COMPLEX (KIND=nag_wp) A(LDA,*), B(LDB,*), WORK(max(1,LWORK))
```

The routine may be called by its LAPACK name **zgelss**.

3   Description

F08KNF (ZGELSS) uses the singular value decomposition (SVD) of A, where A is an m by n matrix which may be rank-deficient.

Several right-hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the m by r right-hand side matrix B and the n by r solution matrix X.

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

5   Parameters

1:    M – INTEGER   *Input*

   On entry: m, the number of rows of the matrix A.

   Constraint: M $\geq$ 0.

2:    N – INTEGER   *Input*

   On entry: n, the number of columns of the matrix A.

   Constraint: N $\geq$ 0.

3: NRHS – INTEGER *Input*

On entry: r, the number of right-hand sides, i.e., the number of columns of the matrices B and X.

Constraint: $\text{NRHS} \geq 0$.

4: A(LDA, *) – COMPLEX (KIND=nag_wp) array *Input/Output*

Note: the second dimension of the array A must be at least $\max(1, \text{N})$.

On entry: the m by n matrix A.

On exit: the first $\min(m, n)$ rows of A are overwritten with its right singular vectors, stored row-wise.

5: LDA – INTEGER *Input*

On entry: the first dimension of the array A as declared in the (sub)program from which F08KNF (ZGELSS) is called.

Constraint: $\text{LDA} \geq \max(1, \text{M})$.

6: B(LDB, *) – COMPLEX (KIND=nag_wp) array *Input/Output*

Note: the second dimension of the array B must be at least $\max(1, \text{NRHS})$.

On entry: the m by r right-hand side matrix B.

On exit: B is overwritten by the n by r solution matrix X. If $m \geq n$ and $\text{RANK} = n$, the residual sum of squares for the solution in the ith column is given by the sum of squares of the modulus of elements $n + 1, \ldots, m$ in that column.

7: LDB – INTEGER *Input*

On entry: the first dimension of the array B as declared in the (sub)program from which F08KNF (ZGELSS) is called.

Constraint: $\text{LDB} \geq \max(1, \text{M}, \text{N})$.

8: S(*) – REAL (KIND=nag_wp) array *Output*

Note: the dimension of the array S must be at least $\max(1, \min(\text{M}, \text{N}))$.

On exit: the singular values of A in decreasing order.

9: RCOND – REAL (KIND=nag_wp) *Input*

On entry: used to determine the effective rank of A. Singular values $\text{S}(i) \leq \text{RCOND} \times \text{S}(1)$ are treated as zero. If $\text{RCOND} < 0$, *machine precision* is used instead.

10: RANK – INTEGER *Output*

On exit: the effective rank of A, i.e., the number of singular values which are greater than $\text{RCOND} \times \text{S}(1)$.

11: WORK($\max(1, \text{LWORK})$) – COMPLEX (KIND=nag_wp) array *Workspace*

On exit: if $\text{INFO} = 0$, the real part of $\text{WORK}(1)$ contains the minimum value of LWORK required for optimal performance.

12: LWORK – INTEGER *Input*

On entry: the dimension of the array WORK as declared in the (sub)program from which F08KNF (ZGELSS) is called.

If LWORK $= -1$, a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued.

Suggested value: for optimal performance, LWORK should generally be larger. Consider increasing LWORK by at least $nb \times \min(M, N)$, where nb is the optimal ***block size***.

Constraint: LWORK ≥ 1 and LWORK $\geq 2 \times \min(M, N) + \max(M, N, NRHS)$.

13: RWORK($*$) – REAL (KIND=nag_wp) array   *Workspace*

    Note: the dimension of the array RWORK must be at least $\max(1, 5 \times \min(M, N))$.

14: INFO – INTEGER   *Output*

    On exit: INFO $= 0$ unless the routine detects an error (see Section 6).

6 Error Indicators and Warnings

INFO < 0

    If INFO $= -i$, argument i had an illegal value. An explanatory message is output, and execution of the program is terminated.

INFO > 0

    The algorithm for computing the SVD failed to converge; if INFO $= i$, i off-diagonal elements of an intermediate bidiagonal form did not converge to zero.

7 Accuracy

See Section 4.5 of Anderson *et al.* (1999) for details.

8 Parallelism and Performance

F08KNF (ZGELSS) is threaded by NAG for parallel execution in multithreaded implementations of the NAG Library.

F08KNF (ZGELSS) makes calls to BLAS and/or LAPACK routines, which may be threaded within the vendor library used by this implementation. Consult the documentation for the vendor library for further information.

Please consult the X06 Chapter Introduction for information on how to control and interrogate the OpenMP environment used within this routine. Please also consult the Users' Note for your implementation for any additional implementation-specific information.

9 Further Comments

The real analogue of this routine is F08KAF (DGELSS).

10 Example

This example solves the linear least squares problem

$$\min_x \|b - Ax\|_2$$

for the solution, x, of minimum norm, where

$$A = \begin{pmatrix} 0.47 - 0.34i & -0.40 + 0.54i & 0.60 + 0.01i & 0.80 - 1.02i \\ -0.32 - 0.23i & -0.05 + 0.20i & -0.26 - 0.44i & -0.43 + 0.17i \\ 0.35 - 0.60i & -0.52 - 0.34i & 0.87 - 0.11i & -0.34 - 0.09i \\ 0.89 + 0.71i & -0.45 - 0.45i & -0.02 - 0.57i & 1.14 - 0.78i \\ -0.19 + 0.06i & 0.11 - 0.85i & 1.44 + 0.80i & 0.07 + 1.14i \end{pmatrix}$$

and

$$b = \begin{pmatrix} -1.08 - 2.59i \\ -2.61 - 1.49i \\ 3.13 - 3.61i \\ 7.33 - 8.01i \\ 9.12 + 7.63i \end{pmatrix}.$$

A tolerance of 0.01 is used to determine the effective rank of A.

Note that the block size (NB) of 64 assumed in this example is not realistic for such a small problem, but should be suitable for large problems.
