NAG Library Function Document

nag_dggqrf (f08zec)

1   Purpose

nag_dggqrf (f08zec) computes a generalized QR factorization of a real matrix pair (A, B), where A is an n by m matrix and B is an n by p matrix.

2   Specification

```
#include <nag.h>
#include <nagf08.h>
```
```
void nag_dggqrf (Nag_OrderType order, Integer n, Integer m, Integer p,
        double a[], Integer pda, double taua[], double b[], Integer pdb,
        double taub[], NagError *fail)
```

3   Description

nag_dggqrf (f08zec) forms the generalized QR factorization of an n by m matrix A and an n by p matrix B

$$A = QR, \quad B = QTZ,$$

where Q is an n by n orthogonal matrix, Z is a p by p orthogonal matrix and R and T are of the form

$$R = \begin{cases} \begin{matrix} & m \\ m \\ n-m \end{matrix} \begin{pmatrix} R_{11} \\ 0 \end{pmatrix}, & \text{if } n \geq m; \\ \begin{matrix} n & m-n \\ n \begin{pmatrix} R_{11} & R_{12} \end{pmatrix} \end{matrix}, & \text{if } n < m, \end{cases}$$

with R_{11} upper triangular,

$$T = \begin{cases} \begin{matrix} p-n & n \\ n \begin{pmatrix} 0 & T_{12} \end{pmatrix} \end{matrix}, & \text{if } n \leq p, \\ \begin{matrix} & p \\ n-p \\ p \end{matrix} \begin{pmatrix} T_{11} \\ T_{21} \end{pmatrix}, & \text{if } n > p, \end{cases}$$

with T_{12} or T_{21} upper triangular.

In particular, if B is square and nonsingular, the generalized QR factorization of A and B implicitly gives the QR factorization of $B^{-1}A$ as

$$B^{-1}A = Z^{\mathrm{T}}\left(T^{-1}R\right).$$

5   Arguments

1:    **order** – Nag_OrderType   *Input*

On entry: the **order** argument specifies the two-dimensional storage scheme being used, i.e., row-major ordering or column-major ordering. C language defined storage is specified by **order** = Nag_RowMajor. See Section 2.3.1.3 in How to Use the NAG Library and its Documentation for a more detailed explanation of the use of this argument.

Constraint: **order** = Nag_RowMajor or Nag_ColMajor.

2:    **n** – Integer   *Input*

On entry: n, the number of rows of the matrices A and B.

Constraint: **n** ≥ 0.

3:    **m** – Integer   *Input*

On entry: m, the number of columns of the matrix A.

Constraint: **m** ≥ 0.

4:    **p** – Integer   *Input*

On entry: p, the number of columns of the matrix B.

Constraint: **p** ≥ 0.

5:    **a**[dim] – double   *Input/Output*

Note: the dimension, *dim*, of the array **a** must be at least

   max(1, **pda** $\times$ **m**) when **order** = Nag_ColMajor;
   max(1, **n** $\times$ **pda**) when **order** = Nag_RowMajor.

The (i, j)th element of the matrix A is stored in

   a[$(j - 1) \times$ **pda** $+ i - 1$] when **order** = Nag_ColMajor;
   a[$(i - 1) \times$ **pda** $+ j - 1$] when **order** = Nag_RowMajor.

On entry: the n by m matrix A.

On exit: the elements on and above the diagonal of the array contain the $\min(n, m)$ by m upper trapezoidal matrix R (R is upper triangular if $n \geq m$); the elements below the diagonal, with the array **taua**, represent the orthogonal matrix Q as a product of $\min(n, m)$ elementary reflectors (see Section 3.3.6 in the f08 Chapter Introduction).

6:    **pda** – Integer   *Input*

On entry: the stride separating row or column elements (depending on the value of **order**) in the array **a**.

Constraints:

   if **order** = Nag_ColMajor, **pda** $\geq$ max(1, **n**);
   if **order** = Nag_RowMajor, **pda** $\geq$ max(1, **m**).

7:     **taua**[**min**(**n**, **m**)] – double   *Output*

       On exit: the scalar factors of the elementary reflectors which represent the orthogonal matrix Q.

8:     **b**[*dim*] – double   *Input/Output*

       Note: the dimension, *dim*, of the array **b** must be at least

$\quad$ max(1, **pdb** × **p**) when **order** = Nag_ColMajor;
$\quad$ max(1, **n** × **pdb**) when **order** = Nag_RowMajor.

       Where $\mathbf{B}(i, j)$ appears in this document, it refers to the array element

$\quad$ **b**[(*j* − 1) × **pdb** + *i* − 1] when **order** = Nag_ColMajor;
$\quad$ **b**[(*i* − 1) × **pdb** + *j* − 1] when **order** = Nag_RowMajor.

       On entry: the n by p matrix B.

       On exit: if $n \leq p$, the upper triangle of the subarray $\mathbf{B}(1 : n, p - n + 1 : p)$ contains the n by n upper triangular matrix T_{12}.

       If $n > p$, the elements on and above the $(n - p)$th subdiagonal contain the n by p upper trapezoidal matrix T; the remaining elements, with the array **taub**, represent the orthogonal matrix Z as a product of elementary reflectors (see Section 3.3.6 in the f08 Chapter Introduction).

9:     **pdb** – Integer   *Input*

       On entry: the stride separating row or column elements (depending on the value of **order**) in the array **b**.

       Constraints:

$\quad$ if **order** = Nag_ColMajor, **pdb** ≥ max(1, **n**);
$\quad$ if **order** = Nag_RowMajor, **pdb** ≥ max(1, **p**).

10:    **taub**[**min**(**n**, **p**)] – double   *Output*

       On exit: the scalar factors of the elementary reflectors which represent the orthogonal matrix Z.

11:    **fail** – NagError *   *Input/Output*

       The NAG error argument (see Section 2.7 in How to Use the NAG Library and its Documentation).

6   Error Indicators and Warnings

NE_ALLOC_FAIL

       Dynamic memory allocation failed.
       See Section 2.3.1.2 in How to Use the NAG Library and its Documentation for further information.

NE_BAD_PARAM

       On entry, argument ⟨*value*⟩ had an illegal value.

NE_INT

       On entry, **m** = ⟨*value*⟩.
       Constraint: **m** ≥ 0.

       On entry, **n** = ⟨*value*⟩.
       Constraint: **n** ≥ 0.

       On entry, **p** = ⟨*value*⟩.
       Constraint: **p** ≥ 0.

On entry, **pda** = ⟨*value*⟩.
Constraint: **pda** > 0.

On entry, **pdb** = ⟨*value*⟩.
Constraint: **pdb** > 0.

NE_INT_2

On entry, **pda** = ⟨*value*⟩ and **m** = ⟨*value*⟩.
Constraint: **pda** ≥ max(1, **m**).

On entry, **pda** = ⟨*value*⟩ and **n** = ⟨*value*⟩.
Constraint: **pda** ≥ max(1, **n**).

On entry, **pdb** = ⟨*value*⟩ and **n** = ⟨*value*⟩.
Constraint: **pdb** ≥ max(1, **n**).

On entry, **pdb** = ⟨*value*⟩ and **p** = ⟨*value*⟩.
Constraint: **pdb** ≥ max(1, **p**).

NE_INTERNAL_ERROR

An internal error has occurred in this function. Check the function call and any array sizes. If the call is correct then please contact NAG for assistance.

An unexpected error has been triggered by this function. Please contact NAG.
See Section 2.7.6 in How to Use the NAG Library and its Documentation for further information.

NE_NO_LICENCE

Your licence key may have expired or may not have been installed correctly.
See Section 2.7.5 in How to Use the NAG Library and its Documentation for further information.

7 Accuracy

The computed generalized QR factorization is the exact factorization for nearby matrices $(A + E)$ and $(B + F)$, where

$$\|E\|_2 = O\,\epsilon\|A\|_2 \quad \text{and} \quad \|F\|_2 = O\,\epsilon\|B\|_2,$$

and ϵ is the *machine precision*.

8 Parallelism and Performance

nag_dggqrf (f08zec) is threaded by NAG for parallel execution in multithreaded implementations of the NAG Library.

nag_dggqrf (f08zec) makes calls to BLAS and/or LAPACK routines, which may be threaded within the vendor library used by this implementation. Consult the documentation for the vendor library for further information.

Please consult the x06 Chapter Introduction for information on how to control and interrogate the OpenMP environment used within this function. Please also consult the Users' Note for your implementation for any additional implementation-specific information.

9 Further Comments

The orthogonal matrices Q and Z may be formed explicitly by calls to nag_dorgqr (f08afc) and nag_dorgrq (f08cjc) respectively. nag_dormqr (f08agc) may be used to multiply Q by another matrix and nag_dormrq (f08ckc) may be used to multiply Z by another matrix.

The complex analogue of this function is nag_zggqrf (f08zsc).

10   Example

This example solves the general Gauss–Markov linear model problem

$$\min_x \|y\|_2 \quad \text{subject to} \quad d = Ax + By$$

where

$$A = \begin{pmatrix} -0.57 & -1.28 & -0.39 \\ -1.93 & 1.08 & -0.31 \\ 2.30 & 0.24 & -0.40 \\ -0.02 & 1.03 & -1.43 \end{pmatrix}, \quad B = \begin{pmatrix} 0.5 & 0 & 0 & 0 \\ 0 & 1.0 & 0 & 0 \\ 0 & 0 & 2.0 & 0 \\ 0 & 0 & 0 & 5.0 \end{pmatrix} \quad \text{and} \quad d = \begin{pmatrix} 1.32 \\ -4.00 \\ 5.52 \\ 3.24 \end{pmatrix}.$$

The solution is obtained by first computing a generalized QR factorization of the matrix pair (A, B). The example illustrates the general solution process, although the above data corresponds to a simple weighted least squares problem.
