

NAG Library Routine Document

F07CNF (ZGTSV)

Note: before using this routine, please read the Users' Note for your implementation to check the interpretation of *bold italicised* terms and other implementation-dependent details.

1 Purpose

F07CNF (ZGTSV) computes the solution to a complex system of linear equations

$$AX = B,$$

where A is an n by n tridiagonal matrix and X and B are n by r matrices.

2 Specification

```
SUBROUTINE F07CNF (N, NRHS, DL, D, DU, B, LDB, INFO)
  INTEGER          N, NRHS, LDB, INFO
  COMPLEX (KIND=nag_wp) DL(*), D(*), DU(*), B(LDB,*)
```

The routine may be called by its LAPACK name *zgtsv*.

3 Description

F07CNF (ZGTSV) uses Gaussian elimination with partial pivoting and row interchanges to solve the equations $AX = B$. The matrix A is factorized as $A = PLU$, where P is a permutation matrix, L is unit lower triangular with at most one nonzero subdiagonal element per column, and U is an upper triangular band matrix, with two superdiagonals.

Note that the equations $A^T X = B$ may be solved by interchanging the order of the arguments DU and DL .

4 References

5 Arguments

- 1: N – INTEGER *Input*
On entry: n , the number of linear equations, i.e., the order of the matrix A .
Constraint: $N \geq 0$.
- 2: NRHS – INTEGER *Input*
On entry: r , the number of right-hand sides, i.e., the number of columns of the matrix B .
Constraint: $NRHS \geq 0$.
- 3: DL(*) – COMPLEX (KIND=nag_wp) array *Input/Output*
Note: the dimension of the array DL must be at least $\max(1, N - 1)$.
On entry: must contain the $(n - 1)$ subdiagonal elements of the matrix A .

On exit: if no constraints are violated, DL is overwritten by the $(n - 2)$ elements of the second superdiagonal of the upper triangular matrix U from the LU factorization of A , in $DL(1), DL(2), \dots, DL(n - 2)$.

4: D(*) – COMPLEX (KIND=nag_wp) array Input/Output

Note: the dimension of the array D must be at least $\max(1, N)$.

On entry: must contain the n diagonal elements of the matrix A .

On exit: if no constraints are violated, D is overwritten by the n diagonal elements of the upper triangular matrix U from the LU factorization of A .

5: DU(*) – COMPLEX (KIND=nag_wp) array Input/Output

Note: the dimension of the array DU must be at least $\max(1, N - 1)$.

On entry: must contain the $(n - 1)$ superdiagonal elements of the matrix A .

On exit: if no constraints are violated, DU is overwritten by the $(n - 1)$ elements of the first superdiagonal of U .

6: B(LDB, *) – COMPLEX (KIND=nag_wp) array Input/Output

Note: the second dimension of the array B must be at least $\max(1, NRHS)$.

Note: to solve the equations $Ax = b$, where b is a single right-hand side, B may be supplied as a one-dimensional array with length $LDB = \max(1, N)$.

On entry: the n by r right-hand side matrix B .

On exit: if $INFO = 0$, the n by r solution matrix X .

7: LDB – INTEGER Input

On entry: the first dimension of the array B as declared in the (sub)program from which F07CNF (ZGTSV) is called.

Constraint: $LDB \geq \max(1, N)$.

8: INFO – INTEGER Output

On exit: $INFO = 0$ unless the routine detects an error (see Section 6).

6 Error Indicators and Warnings

$INFO < 0$

If $INFO = -i$, argument i had an illegal value. An explanatory message is output, and execution of the program is terminated.

$INFO > 0$

Element $\langle value \rangle$ of the diagonal is exactly zero, and the solution has not been computed. The factorization has not been completed unless $N = \langle value \rangle$.

7 Accuracy

The computed solution for a single right-hand side, \hat{x} , satisfies an equation of the form

$$(A + E)\hat{x} = b,$$

where

$$\|E\|_1 = O(\epsilon)\|A\|_1$$

and ϵ is the *machine precision*. An approximate error bound for the computed solution is given by

$$\frac{\|\hat{x} - x\|_1}{\|x\|_1} \leq \kappa(A) \frac{\|E\|_1}{\|A\|_1},$$

where $\kappa(A) = \|A^{-1}\|_1 \|A\|_1$, the condition number of A with respect to the solution of the linear equations. See Section 4.4 of Anderson *et al.* (1999) for further details.

Alternatives to F07CNF (ZGTSV), which return condition and error estimates are F04CCF and F07CPF (ZGTSVX).

8 Parallelism and Performance

F07CNF (ZGTSV) is not threaded in any implementation.

9 Further Comments

The total number of floating-point operations required to solve the equations $AX = B$ is proportional to nr .

The real analogue of this routine is F07CAF (DGTSV).

10 Example

This example solves the equations

$$Ax = b,$$

where A is the tridiagonal matrix

$$A = \begin{pmatrix} -1.3 + 1.3i & 2.0 - 1.0i & 0 & 0 & 0 \\ 1.0 - 2.0i & -1.3 + 1.3i & 2.0 + 1.0i & 0 & 0 \\ 0 & 1.0 + 1.0i & -1.3 + 3.3i & -1.0 + 1.0i & 0 \\ 0 & 0 & 2.0 - 3.0i & -0.3 + 4.3i & 1.0 - 1.0i \\ 0 & 0 & 0 & 1.0 + 1.0i & -3.3 + 1.3i \end{pmatrix}$$

and

$$b = \begin{pmatrix} 2.4 - 5.0i \\ 3.4 + 18.2i \\ -14.7 + 9.7i \\ 31.9 - 7.7i \\ -1.0 + 1.6i \end{pmatrix}.$$
