

NAG Library Routine Document

F08NVF (ZGEBAL)

Note: before using this routine, please read the Users' Note for your implementation to check the interpretation of *bold italicised* terms and other implementation-dependent details.

1 Purpose

F08NVF (ZGEBAL) balances a complex general matrix in order to improve the accuracy of computed eigenvalues and/or eigenvectors.

2 Specification

```
SUBROUTINE F08NVF (JOB, N, A, LDA, ILO, IHI, SCALE, INFO)
INTEGER          N, LDA, ILO, IHI, INFO
REAL (KIND=nag_wp) SCALE(N)
COMPLEX (KIND=nag_wp) A(LDA,*)
CHARACTER(1)     JOB
```

The routine may be called by its LAPACK name *zgebal*.

3 Description

F08NVF (ZGEBAL) balances a complex general matrix A . The term ‘balancing’ covers two steps, each of which involves a similarity transformation of A . The routine can perform either or both of these steps.

1. The routine first attempts to permute A to block upper triangular form by a similarity transformation:

$$PAP^T = A' = \begin{pmatrix} A'_{11} & A'_{12} & A'_{13} \\ 0 & A'_{22} & A'_{23} \\ 0 & 0 & A'_{33} \end{pmatrix}$$

where P is a permutation matrix, and A'_{11} and A'_{33} are upper triangular. Then the diagonal elements of A'_{11} and A'_{33} are eigenvalues of A . The rest of the eigenvalues of A are the eigenvalues of the central diagonal block A'_{22} , in rows and columns i_{lo} to i_{hi} . Subsequent operations to compute the eigenvalues of A (or its Schur factorization) need only be applied to these rows and columns; this can save a significant amount of work if $i_{lo} > 1$ and $i_{hi} < n$. If no suitable permutation exists (as is often the case), the routine sets $i_{lo} = 1$ and $i_{hi} = n$, and A'_{22} is the whole of A .

2. The routine applies a diagonal similarity transformation to A' , to make the rows and columns of A'_{22} as close in norm as possible:

$$A'' = DA'D^{-1} = \begin{pmatrix} I & 0 & 0 \\ 0 & D_{22} & 0 \\ 0 & 0 & I \end{pmatrix} \begin{pmatrix} A'_{11} & A'_{12} & A'_{13} \\ 0 & A'_{22} & A'_{23} \\ 0 & 0 & A'_{33} \end{pmatrix} \begin{pmatrix} I & 0 & 0 \\ 0 & D_{22}^{-1} & 0 \\ 0 & 0 & I \end{pmatrix}.$$

This scaling can reduce the norm of the matrix (i.e., $\|A''_{22}\| < \|A'_{22}\|$) and hence reduce the effect of rounding errors on the accuracy of computed eigenvalues and eigenvectors.

5 Arguments

- 1: JOB – CHARACTER(1) *Input*
On entry: indicates whether A is to be permuted and/or scaled (or neither).
 JOB = 'N'
 A is neither permuted nor scaled (but values are assigned to ILO, IHI and SCALE).
 JOB = 'P'
 A is permuted but not scaled.
 JOB = 'S'
 A is scaled but not permuted.
 JOB = 'B'
 A is both permuted and scaled.
Constraint: JOB = 'N', 'P', 'S' or 'B'.
- 2: N – INTEGER *Input*
On entry: n , the order of the matrix A .
Constraint: $N \geq 0$.
- 3: A(LDA,*) – COMPLEX (KIND=nag_wp) array *Input/Output*
Note: the second dimension of the array A must be at least $\max(1, N)$.
On entry: the n by n matrix A .
On exit: A is overwritten by the balanced matrix. If JOB = 'N', A is not referenced.
- 4: LDA – INTEGER *Input*
On entry: the first dimension of the array A as declared in the (sub)program from which F08NVF (ZGEBAL) is called.
Constraint: $LDA \geq \max(1, N)$.
- 5: ILO – INTEGER *Output*
 6: IHI – INTEGER *Output*
On exit: the values i_{lo} and i_{hi} such that on exit $A(i, j)$ is zero if $i > j$ and $1 \leq j < i_{lo}$ or $i_{hi} < i \leq n$.
 If JOB = 'N' or 'S', $i_{lo} = 1$ and $i_{hi} = n$.
- 7: SCALE(N) – REAL (KIND=nag_wp) array *Output*
On exit: details of the permutations and scaling factors applied to A . More precisely, if p_j is the index of the row and column interchanged with row and column j and d_j is the scaling factor used to balance row and column j then
- $$\text{SCALE}(j) = \begin{cases} p_j, & j = 1, 2, \dots, i_{lo} - 1 \\ d_j, & j = i_{lo}, i_{lo} + 1, \dots, i_{hi} \quad \text{and} \\ p_j, & j = i_{hi} + 1, i_{hi} + 2, \dots, n. \end{cases}$$
- The order in which the interchanges are made is n to $i_{hi} + 1$ then 1 to $i_{lo} - 1$.
- 8: INFO – INTEGER *Output*
On exit: INFO = 0 unless the routine detects an error (see Section 6).

6 Error Indicators and Warnings

INFO < 0

If INFO = $-i$, argument i had an illegal value. An explanatory message is output, and execution of the program is terminated.

7 Accuracy

The errors are negligible, compared with those in subsequent computations.

8 Parallelism and Performance

F08NVF (ZGEBAL) makes calls to BLAS and/or LAPACK routines, which may be threaded within the vendor library used by this implementation. Consult the documentation for the vendor library for further information.

Please consult the X06 Chapter Introduction for information on how to control and interrogate the OpenMP environment used within this routine. Please also consult the Users' Note for your implementation for any additional implementation-specific information.

9 Further Comments

If the matrix A is balanced by F08NVF (ZGEBAL), then any eigenvectors computed subsequently are eigenvectors of the matrix A'' (see Section 3) and hence F08NWF (ZGEBAK) **must** then be called to transform them back to eigenvectors of A .

If the Schur vectors of A are required, then this routine must **not** be called with JOB = 'S' or 'B', because then the balancing transformation is not unitary. If this routine is called with JOB = 'P', then any Schur vectors computed subsequently are Schur vectors of the matrix A'' , and F08NWF (ZGEBAK) **must** be called (with SIDE = 'R') to transform them back to Schur vectors of A .

The total number of real floating-point operations is approximately proportional to n^2 .

The real analogue of this routine is F08NHF (DGEBAL).

10 Example

This example computes all the eigenvalues and right eigenvectors of the matrix A , where

$$A = \begin{pmatrix} 1.50 - 2.75i & 0.00 + 0.00i & 0.00 + 0.00i & 0.00 + 0.00i \\ -8.06 - 1.24i & -2.50 - 0.50i & 0.00 + 0.00i & -0.75 + 0.50i \\ -2.09 + 7.56i & 1.39 + 3.97i & -1.25 + 0.75i & -4.82 - 5.67i \\ 6.18 + 9.79i & -0.92 - 0.62i & 0.00 + 0.00i & -2.50 - 0.50i \end{pmatrix}.$$

The program first calls F08NVF (ZGEBAL) to balance the matrix; it then computes the Schur factorization of the balanced matrix, by reduction to Hessenberg form and the QR algorithm. Then it calls F08QXF (ZTREVC) to compute the right eigenvectors of the balanced matrix, and finally calls F08NWF (ZGEBAK) to transform the eigenvectors back to eigenvectors of the original matrix A .
