## nag\_numdiff\_1d\_real\_eval (d04bac)

### 1 Purpose

nag\_numdiff\_1d\_real\_eval (d04bac) calculates a set of derivatives (up to order 14) of a function at a point with respect to a single variable. A corresponding set of error estimates is also returned. Derivatives are calculated using an extension of the Neville algorithm. This function differs from nag\_numdiff\_1d\_real (d04aac), in that the abscissae and corresponding function values must be calculated before this function is called. The abscissae may be generated using nag\_numdiff\_1d\_real\_absci (d04bbc).

### 2 Specification

```
#include <nag.h>
#include <nagd04.h>

void nag_numdiff_1d_real_eval (const double xval[], const double fval[],
                               double der[], double ertest[], NagError *fail)
```

### 3 Description

nag\_numdiff\_1d\_real\_eval (d04bac) provides a set of approximations:

$$\mathbf{der}[j - 1], \quad j = 1, 2, \dots, 14$$

to the derivatives:

$$f^{(j)}(x_0), \quad j = 1, 2, \dots, 14$$

of a real valued function  $f(x)$  at a real abscissa  $x_0$ , together with a set of error estimates:

$$\mathbf{erest}[j - 1], \quad j = 1, 2, \dots, 14$$

which hopefully satisfy:

$$|\mathbf{der}[j - 1] - f^{(j)}(x_0)| < \mathbf{erest}[j - 1], \quad j = 1, 2, \dots, 14.$$

The results  $\mathbf{der}[j - 1]$  and  $\mathbf{erest}[j - 1]$  are based on 21 function values:

$$f(x_0), f(x_0 \pm (2i - 1)h), \quad i = 1, 2, \dots, 10.$$

The abscissae  $x$  and the corresponding function values  $f(x)$  should be passed into nag\_numdiff\_1d\_real\_eval (d04bac) as the vectors  $\mathbf{xval}$  and  $\mathbf{fval}$  respectively. The step size  $h$  is derived from the abscissae in  $\mathbf{xval}$ . See Section 9 for a discussion of how the derived value of  $h$  may affect the results of nag\_numdiff\_1d\_real\_eval (d04bac). The order in which the abscissae and function values are stored in  $\mathbf{xval}$  and  $\mathbf{fval}$  is irrelevant, provided that the function value at any given index corresponds to the value of the abscissa at the same index. Abscissae may be automatically generated using nag\_numdiff\_1d\_real\_absci (d04bbc) if desired. For each derivative nag\_numdiff\_1d\_real\_eval (d04bac) employs an extension of the Neville Algorithm (see Lyness and Moler (1969)) to obtain a selection of approximations.

For example, for odd derivatives, this function calculates a set of numbers:

$$T_{k,p,s}, \quad p = s, s + 1, \dots, 6, \quad k = 0, 1, \dots, 9 - p$$

each of which is an approximation to  $f^{(2s+1)}(x_0)/(2s+1)!$ . A specific approximation  $T_{k,p,s}$  is of polynomial degree  $2p+2$  and is based on polynomial interpolation using function values  $f(x_0 \pm (2i - 1)h)$ , for  $k = k, \dots, k + p$ . In the absence of round-off error, the better approximations would be associated with the larger values of  $p$  and of  $k$ . However, round-off error in function values

has an increasingly contaminating effect for successively larger values of  $p$ . This function proceeds to make a judicious choice between all the approximations in the following way.

For a specified value of  $s$ , let:

$$R_p = U_p - L_p, \quad p = s, s + 1, \dots, 6$$

where  $U_p = \max_k(T_{k,p,s})$  and  $L_p = \min_k(T_{k,p,s})$ , for  $k = 0, 1, \dots, 9 - p$ , and let  $\bar{p}$  be such that  $R_{\bar{p}} = \min_p(R_p)$ , for  $p = s, \dots, 6$ .

This function returns:

$$\mathbf{der}[2s] = \frac{1}{8 - \bar{p}} \times \left\{ \sum_{k=0}^{9-\bar{p}} T_{k,\bar{p},s} - U_{\bar{p}} - L_{\bar{p}} \right\} (2s + 1)!$$

and

$$\mathbf{erest}[2s] = R_{\bar{p}} \times (2s + 1)! \times K_{2s+1}$$

where  $K_j$  is a safety factor which has been assigned the values:

$$\begin{aligned} K_j &= 1, & j &\leq 9 \\ K_j &= 1.5, & j &= 10, 11 \\ K_j &= 2 & j &\geq 12, \end{aligned}$$

on the basis of performance statistics.

The even order derivatives are calculated in a precisely analogous manner.

## 5 Arguments

- 1: **xval[21]** – const double *Input*  
*On entry:* the abscissae at which the function has been evaluated, as described in Section 3. These can be generated by calling `nag_numdiff_1d_real_absci` (d04bbc). The order of the abscissae is irrelevant.  
*Constraint:* the values in **xval** must span the set  $\{x_0, x_0 \pm (2j - 1)h\}$ , for  $j = 1, 2, \dots, 10$ .
- 2: **fval[21]** – const double *Input*  
*On entry:* **fval**[ $j - 1$ ] must contain the function value at **xval**[ $j - 1$ ], for  $j = 1, 2, \dots, 21$ .
- 3: **der[14]** – double *Output*  
*On exit:* the 14 derivative estimates.
- 4: **erest[14]** – double *Output*  
*On exit:* the 14 error estimates for the derivatives.
- 5: **fail** – NagError \* *Input/Output*  
The NAG error argument (see Section 2.7 in How to Use the NAG Library and its Documentation).

## 6 Error Indicators and Warnings

### NE\_ALLOC\_FAIL

Dynamic memory allocation failed.

See Section 3.2.1.2 in How to Use the NAG Library and its Documentation for further information.

### NE\_BAD\_PARAM

On entry, argument  $\langle value \rangle$  had an illegal value.

### NE\_INTERNAL\_ERROR

An internal error has occurred in this function. Check the function call and any array sizes. If the call is correct then please contact NAG for assistance.

An unexpected error has been triggered by this function. Please contact NAG.

See Section 3.6.6 in How to Use the NAG Library and its Documentation for further information.

### NE\_NO\_LICENCE

Your licence key may have expired or may not have been installed correctly.

See Section 3.6.5 in How to Use the NAG Library and its Documentation for further information.

### NE\_SPACING\_INCORRECT

On entry, the values of **xval** are not correctly spaced.

Derived  $h = \langle value \rangle$ .

### NE\_TOO\_SMALL

The derived  $h$  is below tolerance.

Derived  $h > \langle value \rangle$  is required. Derived  $h = \langle value \rangle$ .

## 7 Accuracy

The accuracy of the results is problem dependent. An estimate of the accuracy of each result **der**[ $j - 1$ ] is returned in **erest**[ $j - 1$ ] (see Sections 3, 5 and 9).

A basic feature of any floating-point function for numerical differentiation based on real function values on the real axis is that successively higher order derivative approximations are successively less accurate. It is expected that in most cases **der**[13] will be unusable. As an aid to this process, the sign of **erest**[ $j - 1$ ] is set negative when the estimated absolute error is greater than the approximate derivative itself, i.e., when the approximate derivative may be so inaccurate that it may even have the wrong sign. It is also set negative in some other cases when information available to `nag_numdiff_1d_real_eval` (d04bac) indicates that the corresponding value of **der**[ $j - 1$ ] is questionable.

The actual values in **erest** depend on the accuracy of the function values, the properties of the machine arithmetic, the analytic properties of the function being differentiated and the step length  $h$  (see Section 9). The only hard and fast rule is that for a given objective function and  $h$ , the values of **erest**[ $j - 1$ ] increase with increasing  $j$ . The limit of 14 is dictated by experience. Only very rarely can one obtain meaningful approximations for higher order derivatives on conventional machines.

## 8 Parallelism and Performance

`nag_numdiff_1d_real_eval` (d04bac) is not threaded in any implementation.

## 9 Further Comments

The results depend very critically on the choice of the step length  $h$ . The overall accuracy is diminished as  $h$  becomes small (because of the effect of round-off error) and as  $h$  becomes large (because the discretization error also becomes large). If this function is used four or five times with different values of  $h$  one can find a reasonably good value. A process in which the value of  $h$  is successively halved (or doubled) is usually quite effective. Experience has shown that in cases in which the Taylor series for the objective function about  $x_0$  has a finite radius of convergence  $R$ , the choices of  $h > R/19$  are not likely to lead to good results. In this case some function values lie outside the circle of convergence.

As mentioned, the order of the abscissae in **xval** does not matter, provided the corresponding values of **fval** are ordered identically. If the abscissae are generated by `nag_numdiff_1d_real_absci` (d04bbc), then they will be in ascending order. In particular, the target abscissa  $x_0$  will be stored in **xval**[10].

## 10 Example

This example evaluates the derivatives of the polygamma function, calculated using `nag_real_polygamma` (s14aec), and compares the first 3 derivatives calculated to those found using `nag_real_polygamma` (s14aec).

## 10.2 Program Data

None.

### 10.3 Program Results

nag\_numdiff\_1d\_real\_eval (d04bac) Example Program Results

Find the derivatives of the polygamma ( $\psi$ ) function using function values generated by nag\_real\_polygamma (s14aec).

Demonstrate the effect of successively reducing hbase.

Derivative (1) calculated using nag\_real\_polygamma (s14aec): 4.0153e+02  
 Derivative and error estimates for derivative (1)

hbase	der[0]	erest[0]
2.5000e-03	4.0204e+02	1.3940e+02
2.5000e-04	4.0153e+02	4.9170e-11
2.5000e-05	4.0153e+02	2.1799e-10
2.5000e-06	4.0153e+02	1.1826e-09

Derivative (2) calculated using nag\_real\_polygamma (s14aec): -1.6002e+04  
 Derivative and error estimates for derivative (2)

hbase	der[1]	erest[1]
2.5000e-03	-1.6022e+04	5.5760e+03
2.5000e-04	-1.6002e+04	1.2831e-07
2.5000e-05	-1.6002e+04	6.0543e-06
2.5000e-06	-1.6002e+04	9.5762e-04

Derivative (3) calculated using nag\_real\_polygamma (s14aec): 9.6001e+05  
 Derivative and error estimates for derivative (3)

hbase	der[2]	erest[2]
2.5000e-03	9.1465e+05	-7.3750e+06
2.5000e-04	9.6001e+05	2.3718e-04
2.5000e-05	9.6001e+05	4.2253e-02
2.5000e-06	9.6001e+05	5.9679e+01
